BioOne Complete (complete.BioOne.org) is a full-text database of 200 subscribed and open-access titles in the biological, ecological, and environmental sciences published by nonprofit societies, associations, museums, institutions, and presses.

Your use of this PDF, the BioOne Complete website, and all posted and associated content indicates your acceptance of BioOne's Terms of Use, available at www.bioone.org/terms-of-use.

Usage of BioOne Complete content is strictly limited to personal, educational, and non - commercial use. Commercial inquiries or rights and permissions requests should be directed to the individual publisher as copyright holder.

BioOne sees sustainable scholarly publishing as an inherently collaborative enterprise connecting authors, nonprofit publishers, academic institutions, research libraries, and research funders in the common goal of maximizing access to critical research.

Larval Nematodes (*Ascarops* sp.) in Stomach Granulomas of the Sagebrush Lizard, *Sceloporus graciosus*

Stephen R. Goldberg¹ and Charles R. Bursey,² ¹ Department of Biology, Whittier College, Whittier, California 90608, USA; ² Department of Biology, Pennsylvania State University, Shenango Valley Campus, Sharon, Pennsylvania 16146, USA

ABSTRACT: Wild populations of the sagebrush lizard (*Sceloporus graciosus*) are reported as paratenic hosts for third stage larvae of *Ascarops* sp. Larvae were found in stomach submucosal granulomas which averaged 350 μ m in diameter and consisted of histiocytes and layers of fibrocytes. Prevalence of infection was 16% (27 of 170 infected); mean intensity was 3 (1 to 8 nematodes/host). Prevalence was significantly higher in male than female lizards.

Key words: Larval nematode, *Ascarops* sp., *Sceloporus graciosus*, sagebrush lizard, granuloma, stomach, pathology.

Animals from all vertebrate classes can be paratenic hosts, especially those that habitually feed on insects (Alicata, 1935; Olsen, 1974). Unfortunately, most of the information about paratenic hosts is limited to a discussion of occurrence. The purpose of this note is to report, for the first time, the occurrence of larvae of the nematode *Ascarops* sp. (Spirurida, Spirocercidae) in the sagebrush lizard (*Sceloporus graciosus*, Iguanidae). Data on prevalence and histopathology of lesions associated with the infection also are described.

One hundred seventy adult sagebrush lizards were collected by noosing during May 1988 on the Windy Gap Trail (elevation 1,889 m; 34°21'N, 117°48'W) in the Crystal Lake area of the San Gabriel Mountains, Los Angeles County, California. Infected stomachs were fixed in neutral buffered 10% formalin, embedded in paraffin, sectioned at 5 μ m and stained with hematoxylin and eosin. Individual nematode larvae were dissected from formalin fixed granulomas and mounted in Hoyer's solution for taxonomic identification. A specimen was deposited in the U.S. National Parasite Collection (Beltsville, Maryland 20705, USA; accession number 80564). In addition, livers of 86

adult sagebrush lizards collected in 1986 and 36 adults from the 1987 and 1988 samples were examined for the presence of larval *Ascarops* sp.

At necropsy, granulomas containing encysted nematode larvae were grossly visible as whitish nodules embedded in the stomach wall. The granulomas (Fig. 1) were thin-walled and consisted of fibrocytes and histiocytes. They were approximately 350 μ m in diameter and were located in the stomach submucosa. An inflammatory response was not seen. Occasional masses of cellular debris, cells with pyknotic nuclei, histiocytes with foamy cytoplasm and heterophils were observed within the granulomas. Some, presumably older, granulomas were undergoing mineralization.

Each granuloma contained a third stage *Ascarops* sp. Larvae were approximately 1.9 mm long and 80 μ m wide. The distinguishing differential features of the third stage larva of *Ascarops* sp. are (1) the right and left anterolateral body walls are prolonged into dorsoventral liplike projections and (2) the tip of the tail possesses a smooth knoblike process. We observed both features in larvae taken from stomach granulomas of sagebrush lizards. Fourth stage larvae or mature worms were not found.

Prevalence of *Ascarops* sp. larvae was 16% (27 infected of 170 hosts examined). Mean intensity was 2.9 (1 to 8 nematodes/host). There was a significant difference in prevalence between males and females (21 of 91 and 6 of 79, respectively; $\chi^2 = 7.9$, 1 df, $P < 0.001$). Mean intensity for males was 3.3 (1 to 8); it was 2.3 (1 to 4) for females. We found no externally visible characteristics that would allow detection of living lizards with granulomas.

FIGURE 1. Larval *Ascarops* sp. within a granuloma in the submucosa of a sagebrush lizard. H&E.

Two of the 86 lizards collected in 1986 had larval *Ascarops* sp. in liver granulomas (prevalence of 2%, one granuloma in each of two livers). Liver granulomas were not found in sagebrush lizards collected in 1987 or 1988. Liver granulomas containing *Ascarops* sp. have been observed in the western fence lizard (*Sceloporus occidentalis*)

where prevalence may reach 37% (Goldberg and Bursey, 1988). It is not known why larval *Ascarops* sp. establish in the stomach wall of sagebrush lizards, but only rarely invade the liver.

Seven species of North American vertebrates have previously been reported as paratenic hosts of *Ascarops* sp. (Table 1).

TABLE 1. Paratenic hosts of *Ascarops* sp.

Species	Location in host	Collection site	Reference
Reptilia: Squamata			
<i>Sceloporus graciosus</i>	stomach wall	California	This study

These insectivorous vertebrates presumably acquire *Ascarops* sp. through their diets. Within the insect intermediate host, first stage larvae are enclosed in thin-walled cysts and development to third stage takes place within the cyst (Olsen, 1974). In a paratenic host, a freed third stage larva migrates through the stomach wall and re-encysts. No further development of the larval nematode occurs; although, normal development could resume should a paratenic host be eaten by a proper definitive host. Larvae have been found to survive as long as 1 yr in mice (Olsen, 1974), but survival time in the sagebrush lizard is not known.

About 20 species from 14 genera of beetles have been identified as intermediate hosts of *Ascarops* sp. (Table 2). The introduction of exotic species of dung beetles to the United States has increased the number of potential intermediate and paratenic hosts. Exotic beetles have become widespread since the initial releases in Texas in 1972 (Blume and Aga, 1978) and can now be found throughout most of Texas and in Louisiana (Fincher and Marti, 1982). Ex-

otic dung beetles are also established in California (Anderson and Loomis, 1978). The specific insect host of *Ascarops* sp. eaten by the sagebrush lizard has not been determined.

We thank H. J. Holshuh (Comparative Medical and Veterinary Services, County of Los Angeles) for discussions on histopathology. T. A. Bienz assisted with fieldwork.
