A Revision of the North American Spider Genus *Anachemmis* Chamberlin (Araneae, Tengellidae)

NORMAN I. PLATNICK¹ AND DARRELL UBICK²

ABSTRACT

Anachemmis Chamberlin is revised, and contains five species from California, Arizona, and Sonora that are hypothesized to represent the sister group of the Appalachian genus *Liocranoides* Keyserling. The male of the southern Californian type species, *A. sober* Chamberlin, is described for the first time, as are both sexes of four new species: *A. linsdalei* from northern and central California, *A. jungi* from caves in Inyo County, California, *A. aalbui* from in and near caves in San Bernardino County, California, and *A. beattyi* from Arizona and Sonora.

INTRODUCTION

This paper is the third in a series on the North American spiders currently assigned to the family Tengellidae, and deals with the species belonging to the genus *Anachemmis* Chamberlin. In his original description, Chamberlin (1919) assigned two species from California to the genus, but they are not actually congeneric. *Anachemmis dolichopus* Chamberlin was chosen as the type species of *Socalchemmis* Platnick and Ubick (2001),

a group comprising 16 described species found in California, Arizona, and Baja California Norte.

Anachemmis itself has remained almost totally unstudied. Roewer (1955: 607) assigned *Chemmis unicolor* Banks (1901) to *Anachemmis*, but examination of the holotype indicates that this transfer was baseless and is incorrect. The type species, *Anachemmis sober* Chamberlin, was described from females only and has never been redescribed, al-

though Silva (2003: fig. 13d) did present a scanning electron micrograph of the male palp, based on some of the material detailed below. Lehtinen (1967: 213) published a synonymy, attributed to the late Wilton Ivie, of *Anachemmis* with *Titiotus* Simon, but that synonymy was rejected by Platnick (1999).

Examination of the available collections has revealed a total of five species belonging to *Anachemmis*, distributed in California, Arizona, and Sonora. The group does not seem to have speciated to anywhere near the extent of either of its western relatives, *Socalchemmis* or *Titiotus*, each of which has a highly diversified Californian fauna. Interestingly, though, its members may actually be more closely related to the Appalachian genus *Liocranoides* Keyserling than to either of the other Californian tengelloid genera. In the analysis by Silva (2003: fig. 6), *Anachemmis* clustered with *Liocranoides* rather than *Titiotus*, based on the presence of a prolateral tegular concavity near the embolic base and a subapical serrula. Although *Socalchemmis* was not included in her analysis, we suspect that it is more closely related to *Titiotus* than to *Anachemmis* or *Liocranoides*, as evidenced by the ventral displacement of the ventral prong of the male retrolateral tibial apophysis.

The familial placement of these genera remains tentative (Platnick, 1999). Silva's (2003) results placed them as the sister group of an assemblage including, among other taxa, the type genera of several family-group names, including three recognized as subfamilies of the Zoropsidae by Raven and Stumkat (2005): the Griswoldiinae, Zorocratinae, and Zoropsinae. Raven and Stumkat's results differ, however, in placing *Tengella* Dahl outside this group (in Silva's cladogram, *Tengella* and *Zorocrates* Simon are sister groups). Unfortunately, none of the other genera currently placed in the Tengellidae were included in the Raven and Stumkat matrix, but it is possible that *Liocranoides* and its western relatives may eventually have to be considered members of the Zoropsidae (which has priority over Tengellidae) or placed in a family separate from each of the family-group name-bearing genera *Zoropsis* Simon, *Tengella*, *Zorocrates*, and

Griswoldia Dippenaar-Schoeman and Jocqué.

Although species of *Anachemmis* differ from those of *Liocranoides* in having the dorsal prong of the male retrolateral tibial apophysis reduced to just a tiny point, and in lacking a separate anterior hood on the female epigynum, the basic structure of both the male palp and female epigynum differs little in the two groups; one could therefore argue that *Anachemmis* is just a junior synonym of *Liocranoides*. Given that each group of species appears to be monophyletic, that they are separated by an extensive geographic gap, and that each group already has an available generic name, we prefer to retain both of those established names. As with *Liocranoides*, some of the species of *Anachemmis* have been taken in caves, and one (*A. jungi*, new species) is so far known only from subterranean habitats.

Specimens have been examined from the collections of the American Museum of Natural History (AMNH), California Academy of Sciences (CAS), Blaine Hebert (CBH), David Bixler (CDB), California Department of Food and Agriculture (CDFA), Darrell Ubick (CDU), Graham Lowe (CGL), James Cokendolpher (JCC), Los Angeles County Museum (LACM), Museum of Comparative Zoology, Harvard University (MCZ), Mel Thompson (MET), University of California, Berkeley (UCB), University of California, Riverside (UCR), Wendell Icenogle (WRI), and B. J. Kaston material currently in WRI (WRIK). The format of the descriptions follows that of Platnick (1999); all measurements are in millimeters.

ANACHEMMIS Chamberlin

Anachemmis Chamberlin, 1919: 12 (type species by original designation *A. sober* Chamberlin).

DIAGNOSIS: The unusual character combination of three claws plus claw tufts (fig. 1) readily separates members of *Anachemmis* and its closest relatives from most other North American spiders. Specimens of *Zorocrates*, which are found from Arizona to Texas and south to Central America, have a tiny remnant of the third claw that is equally obscured by the distal hairs of the tarsal scopula, but *Zorocrates* species lack true

Figs. 1–4. *Anachemmis linsdalei*, new species, male. **1.** Tarsus II, distal view, with claw tuft of one side shaved off. **2, 4.** Tarsus III, distal view, showing small unpaired claw. **3.** Tarsus III, lateral view, showing scopula, claw tufts, and trichobothria. Scale bar = 43 μm (2), 100 μm (1), 150 μm (4), 600 μm (3).

Figs. 5–8. *Anachemmis linsdalei*, new species, male. **5, 6.** Trichobothrial base from palpal tibia, dorsal view. **7.** Tarsus III, dorsal view, showing trichobothrial base and tarsal organ. **8.** Tarsal organ from tarsus III, dorsal view. Scale bar = 7.5 μm (8), 15 μm (5, 6), 25 μm (7).

claw tufts (Griswold et al., in press) and have a single retrolateral tibial apophysis on the male palp. Males of *Anachemmis* differ from those of *Titiotus* in having two rather than three or four prongs on the retrolateral tibial

apophysis, and from those of *Socalchemmis* and *Liocranoides* by having a flattened, blade-shaped ventral prong of the apophysis and by having the dorsal prong of the apophysis reduced to a small point. The female epi-

Figs. 9–12. *Anachemmis linsdalei*, new species, female. **9.** Spinnerets of left side, distal view. **10.** Left anterior lateral spinneret, distal view. **11.** Left posterior median spinneret, distal view. **12.** Left posterior lateral spinneret, distal view. Scale bar = 60 μm (10), 77 μm (12), 100 μm (11), 200 μm (9).

gynum differs from those of *Liocranoides* species in lacking an anterior hood, from those of *Titiotus* species in having a much smaller septum, and from those of *Socal-*

chemmis species in having *Liocranoides*-like anterior vulval elaborations.

DESCRIPTION: Medium to large spiders, total length of males 7–10, of females 8–13.

Figs. 13–16. *Anachemmis linsdalei*, new species, male. **13.** Spinnerets of left side, distal view. **14.** Left anterior lateral spinneret, distal view. **15.** Left posterior median spinneret, distal view. **16.** Left posterior lateral spinneret, distal view. Scale bar = 43 μm (14–16), 150 μm (13).

Carapace oval, widest at rear of coxae II, abruptly narrowed at level of palpi to less than two-thirds of maximum width; thoracic groove long, longitudinal, very deep; surface coated with short recumbent and fewer, lon-

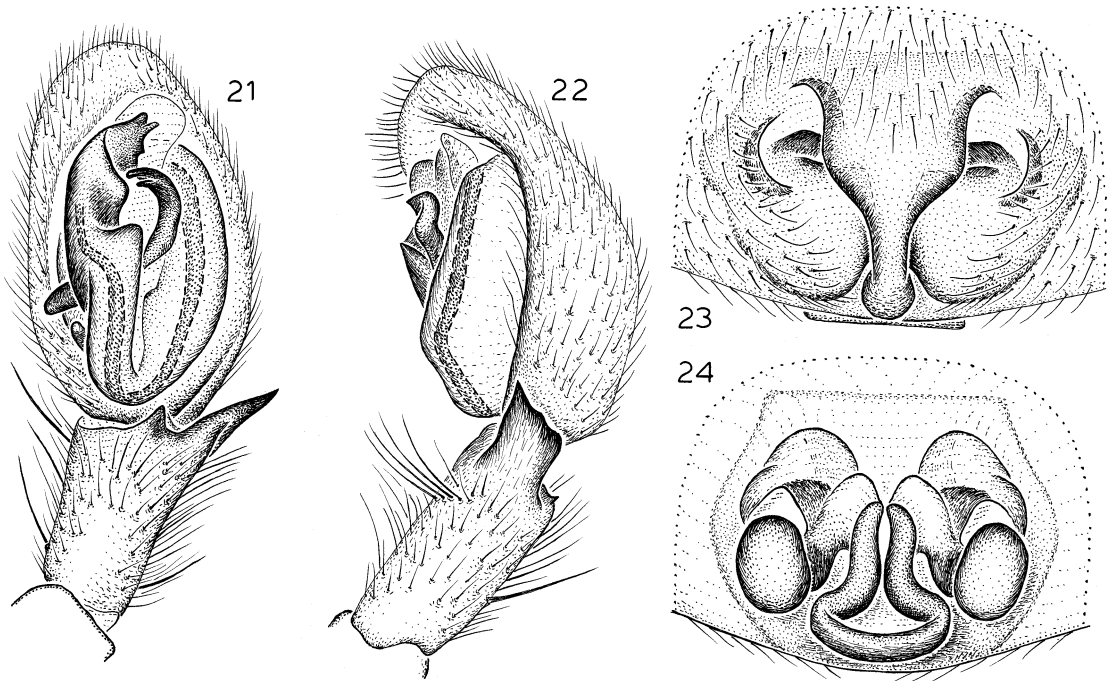

ger, erect dark setae, erect setae most numerous along midline and in ocular area; eight eyes in two rows; from above, both eye rows slightly recurved; from front, anterior row recurved, posterior row slightly pro-

Figs. 17–20. *Anachemmis linsdalei*, new species, male. **17.** Left palp, prolateral view, showing interlocking lobes on tegulum and subtegulum. **18.** Left palp, retrolateral view. **19.** Left palp, ventral view. **20.** Left embolus, conductor, and median apophysis, ventral view. Scale bar = 200 μm (20), 600 μm (17–19).

curved; anterior median eyes round, smallest; other eyes oval, subequal, with canoe-shaped tapeta; anterior median eyes separated by roughly their diameter, slightly closer to an-

terior laterals; posterior medians separated by roughly their diameter, farther from posterior laterals; lateral eyes of each side separated by less than their diameter; median ocular

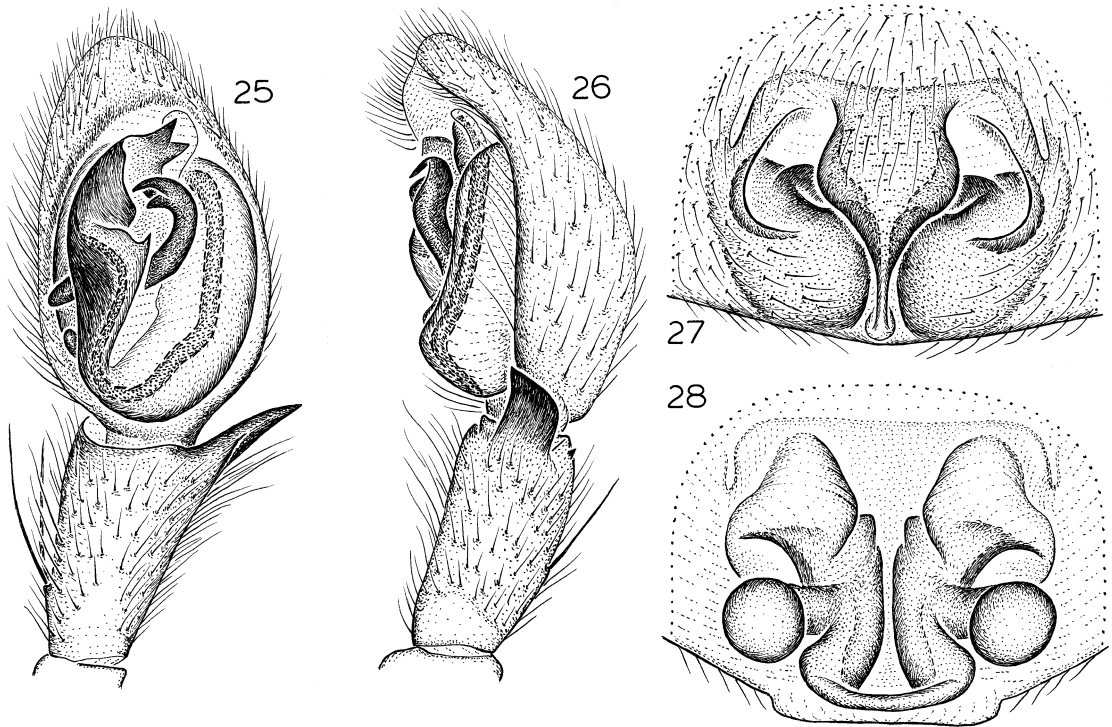

Figs. 21–24. *Anachemmis sober* Chamberlin. **21.** Left male palp, ventral view. **22.** Same, retrolateral view. **23.** Epigynum, ventral view. **24.** Same, dorsal view.

quadrangle wider in back than in front, wider in back than long; clypeal height about twice diameter of anterior median eyes, corners of clypeus with incised margins that overlie cheliceral boss; chilum weakly sclerotized, divided, composed of two triangular sclerites. Chelicerae vertical, anterior surface with few, erect setae; promargin with three teeth situated at proximal end of fang furrow, most proximal tooth smallest, retromargin with three larger, more distally situated teeth; very short, narrow, I-shaped posterior sclerite present, separating chelicerae at base. Labium short, distally invaginated at middle, reflexed at almost 90° angle relative to sternum. Endites rectangular, distally slightly convergent, with anteromedian scopula and anterolateral serrula consisting of single row of teeth. Sternum rounded, without extensions to or between coxae, with erect setae; posterior margin only slightly extended between coxae IV.

Leg formula 4123. Typical leg spination pattern (only surfaces bearing spines listed): femora: I d1-1-1, p01-1, r1-2-1; II d1-1-1, p0-2-1, r1-2-1; III d1-1-1, p2-1-1, r1-2-1; IV

d1-1-1, p2-1-1, r0-0-1; patellae III, IV p0-1-0, r0-1-0; tibiae: I, II p0-1-0, v4-4-2; III, IV d1-0-1, p0-1-1, v2-2-2, r0-1-1; metatarsi: I, II v2-2-2; III p1-1-2, v2-2-1r, r1-1-2; IV p1-1-2, v2-2-1r, r1-2-2; tarsi with three claws and claw tufts (figs. 1–4), superior claws with several weak teeth, most distal teeth largest, inferior claws unarmed; all tarsi with strong ventral scopulae, scopular hairs distinct from those of claw tufts (fig. 1); distal segments with trichobothria in two rows, bases ridged (figs. 5, 6); tarsal organ capsulate (fig. 8); all trochanters strongly notched; males without tibial crack; metatarsi without preening combs.

Abdomen without anterior or dorsal scutum; anterior lateral spinnerets large, composed of two articles (figs. 9, 13), distal article with two major ampullate gland spigots and about 10 small piriform gland spigots (figs. 10, 14); posterior median spinnerets composed of one article, small, triangular (figs. 11, 15), those of female expanded posteriorly, where they bear single large and three or four smaller cylindrical gland spigots, preceded anteriorly by smaller aciniform

Figs. 25–28. *Anachemmis linsdalei*, new species. 25. Left male palp, ventral view. 26. Same, retrolateral view. 27. Epigynum, ventral view. 28. Same, dorsal view.

spigots and at least two larger minor ampullate gland spigots; posterior lateral spinnerets composed of two articles, distal article about one-fifth as long as proximal article, that of female apparently without cylindrical gland spigots at base, in both sexes with smaller spigots around base and on tip (figs. 12, 16); colulus represented by setae on small lobe.

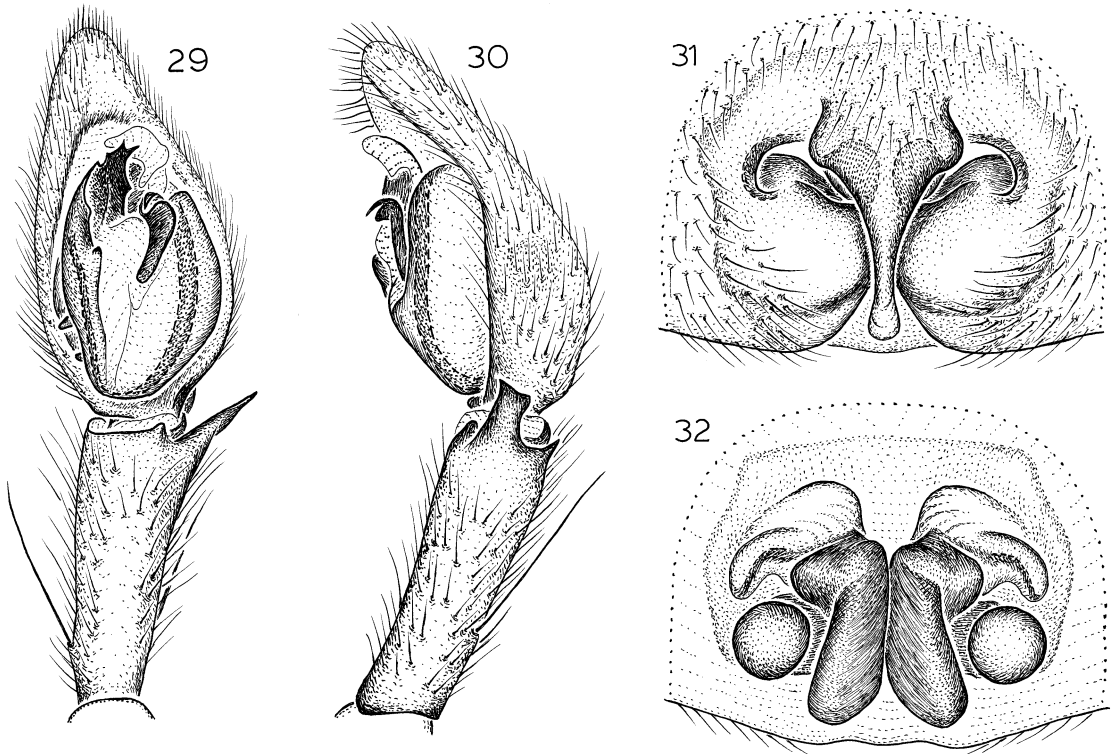

Male palp with patella not widened, retrolateral tibial apophysis bipartite, ventral prong large, blade-shaped (fig. 18), dorsal prong reduced to tiny point; subtegulum and tegulum with interlocking lobes (fig. 17), median apophysis heavily sclerotized at least distally, embolus short, with shallow division between prolateral prong and copulatory prong, accompanied by hyaline conductor (figs. 19, 20). Female palp with extremely long, dentate claw. Epigynum with large median septum wider anteriorly than posteriorly; spermathecal bulbs situated posterolaterally.

MISPLACED SPECIES: *Anachemmis dolichopus* Chamberlin (1919) is now placed in *So-*

calchemmis Platnick and Ubick (2001). For unknown reasons, Roewer (1955) listed *Chemmis unicolor* Banks (1901) as a member of *Anachemmis*, but that transfer is incorrect; the placement of Banks' species will be discussed in detail in a subsequent paper in this series.

KEY TO SPECIES OF *ANACHEMMIS*

- 1. Males 2
- Females 6
- 2. Tegulum much wider opposite median apophysis than elsewhere (figs. 21, 25) 3
- Tegulum not much wider opposite median apophysis than elsewhere (figs. 29, 33, 37) 4
- 3. Tegular edge opposite median apophysis base rounded (fig. 21) *sober*
- Tegular edge opposite median apophysis base pointed (fig. 25) *linsdalei*
- 4. Ventral prong of retrolateral tibial apophysis relatively wide at base (fig. 34) .. *aalbui*
- Ventral prong of retrolateral tibial apophysis relatively narrow at base (figs. 30, 38) ... 5

Figs. 29–32. *Anachemmis jungi*, new species. 29. Left male palp, ventral view. 30. Same, retrolateral view. 31. Epigynum, ventral view. 32. Same, dorsal view.

- 5. Dorsal prong of retrolateral tibial apophysis relatively large (fig. 30) *jungi*
- Dorsal prong of retrolateral tibial apophysis a tiny spur (fig. 38) *beattyi*
- 6. Widened anterior portion of median epigynal septum relatively short (figs. 31, 35) 7
- Widened anterior portion of median epigynal septum relatively long (figs. 23, 27, 39) 8
- 7. Epigynal surface opposite sides of median septum with distinct ridge (fig. 35) *aalbui*
- Epigynal surface opposite sides of median septum without distinct ridge (fig. 31) *jungi*
- 8. Widened portion of epigynal septum with paramedian invaginations (fig. 39) *beattyi*
- Widened portion of epigynal septum without paramedian invaginations (figs. 23, 27) 9
- 9. Epigynal septum relatively wide both anteriorly and posteriorly (fig. 23) *sober*
- Epigynal septum relatively narrow both an-

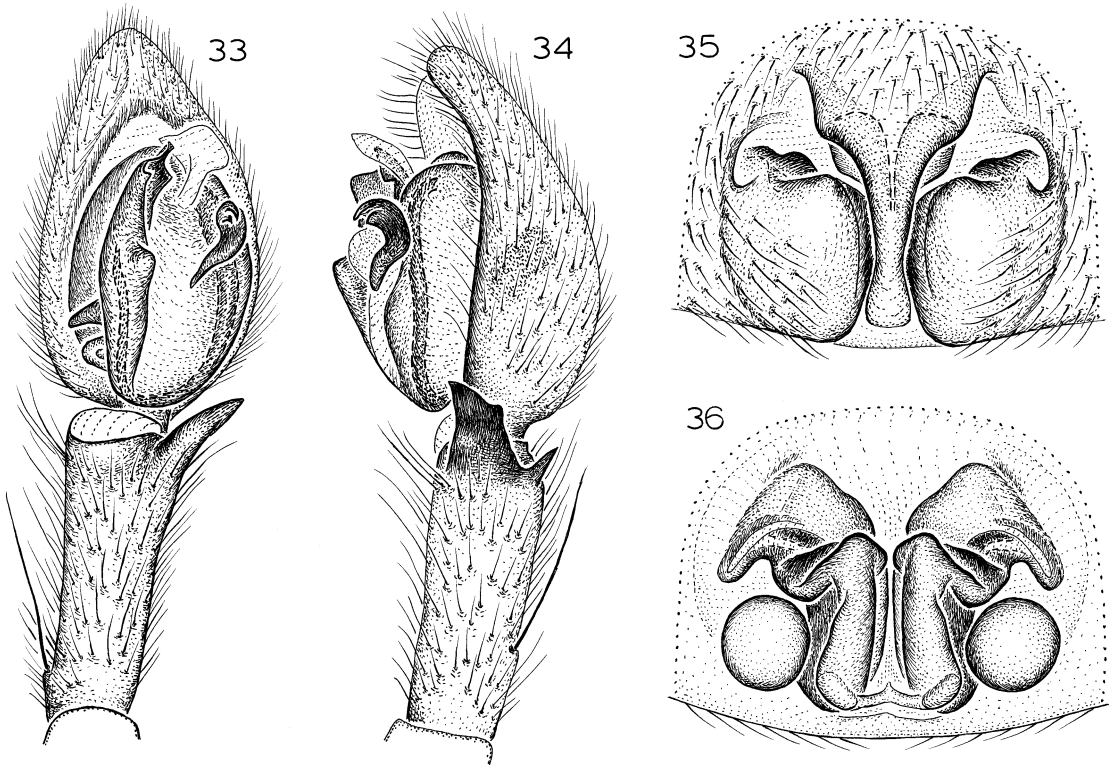

- teriorly and posteriorly (fig. 27) *linsdalei*

Anachemmis sober Chamberlin
 Figures 21–24; Map 1

Anachemmis sober Chamberlin, 1919: 13, pl. 5, fig. 5 (female holotype from Claremont, Los Angeles Co., California, in MCZ, examined).—Silva, 2003: 41, fig. 13d (scanning electron micrograph of male palp).
Anachemmis scaber (lapsus): Roewer, 1955: 607.

DIAGNOSIS: Males closely resemble those of *A. linsdalei* but differ in having a rounded tegular edge opposite the median apophysis (fig. 21); females also closely resemble those of *A. linsdalei* but have a wider epigynal septum and more anteriorly restricted lateral epigynal margins (fig. 23).

MALE: Total length 8.0. Carapace light brown, with darker triangular markings radiating from thoracic groove to intercoxal areas; abdomen mottled brownish gray; femora

Figs. 33–36. *Anachemmis aalbui*, new species. 33. Left male palp, ventral view. 34. Same, retrolateral view. 35. Epigynum, ventral view. 36. Same, dorsal view.

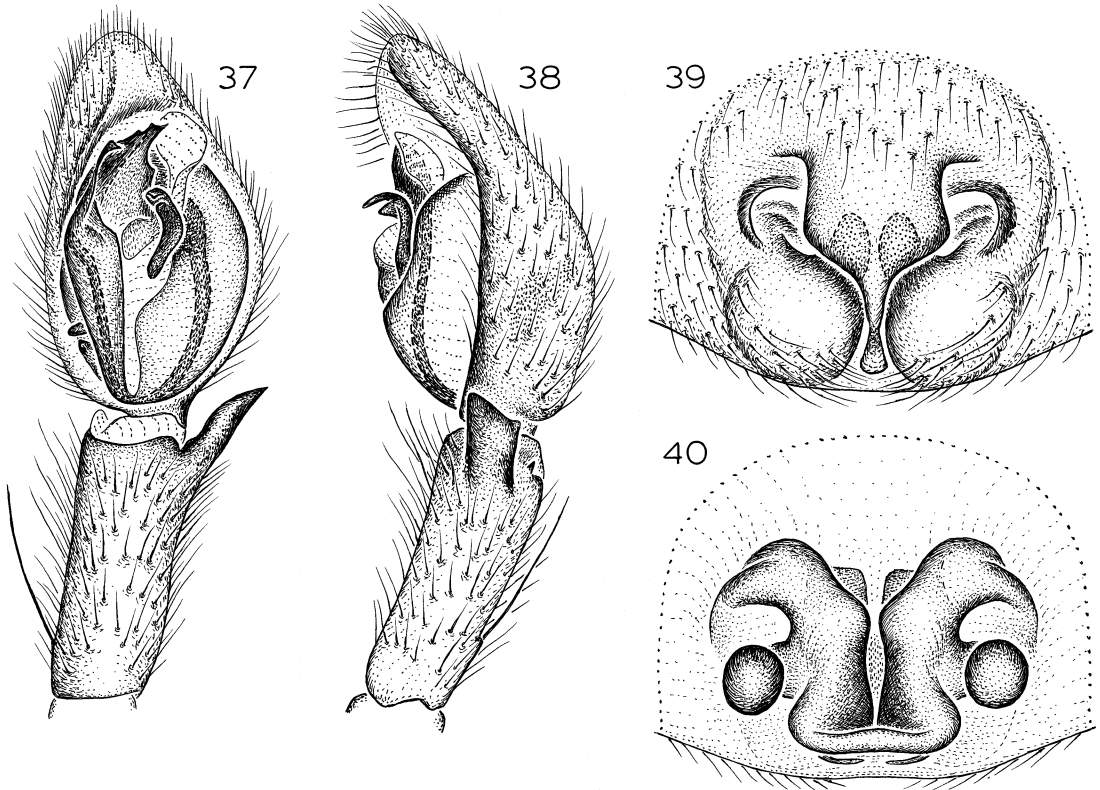

light brown, more distal leg segments grading to dark reddish brown on metatarsi and tarsi. Leg spination: femora: II p1-2-1; IV r0-0-2; tibiae: I d1-0-1, r0-1-0; II d0-0-1, r0-1-0; tibiae: I, II p1-1-0, r1-1-0; III p1-2-2; IV v2-2-2. Tegulum widened opposite median apophysis, with rounded edge (fig. 21); dorsal prong of retrolateral tibial apophysis reduced to tiny, sharp point tip (fig. 22).

FEMALE: Total length 10.3. Coloration as in male. Leg spination: femora: III r1-1-2; IV r0-0-1; tibiae I p0-0-0; III p1-2-2; IV v2-2-2. Epigynum with median septum widened anteriorly and posteriorly, lateral margins restricted to anterior portion of epigynum (fig. 23); spermathecal bulbs oval (fig. 24).

VARIATION: One male taken at Shortcut on the Angeles Crest Highway in the San Gabriel Mountains of Los Angeles County differs from other specimens in having a longer dorsal prong of the retrolateral tibial apophysis. One female from the nearby locality of Switzers Camp differs from most others in

having the lateral epigynal bulges relatively “deflated”. The geographic congruence of these specimens suggested that a separate species might be present in the San Gabriels, but thanks to the help of Wendell Icenogle, a good series of specimens from these and nearby localities has now been available for study. No other males show the abnormally long dorsal prong of the tibial apophysis, and no consistent differences have been detected among the palpal bulbs of any of these specimens. Another female shows the relatively “deflated” lateral epigynal bulges, but only on one side of the epigynum. We conclude that there is evidence for the existence of only a single species at these sites. Another male from Lake Fulmor in Riverside County has a relatively truncated left embolus tip, but is presumably either broken or represents a developmental deformity, as the right embolus of that specimen appears normal.

MATERIAL EXAMINED: CALIFORNIA: **Inyo**

Lowe, CGL), 1 ♂.

DISTRIBUTION: Southern California (map 1).

NATURAL HISTORY: Collection records indicate that *Anachemmis sober* occurs in forests, primarily oak but also coniferous, at elevations from 70 to 2000 m. Specimens have

been found beneath rocks, logs, and other ground litter, in and on leaf litter, on tree trunks, in a cave entrance, and in human structures, such as houses, culverts, and a flume. Several collections are from pitfall and malaise traps and of dead individuals in spider webs, including those of *Latrodectus* and *Steatoda*. The 700 specimens examined indicate that both sexes occur year round, with females being more commonly collected, and a peak abundance from May to August (chart 1). That this species may be very common is documented by a single June day's collection, at Tanbark Flats, Los Angeles County, of 95 males and 130 females.

Anachemmis linsdalei, new species

Figures 1–20, 25–28; Map 1

TYPES: Male holotype and female allotype taken in house at Hastings Natural History State Reserve, Monterey Co., California (Jan. 24–25, 1946; J. Linsdale), deposited in AMNH.

ETYMOLOGY: The specific name is a patronym in honor of the collector of the types and many other specimens.

DIAGNOSIS: Males closely resemble those of *A. sober* but differ in having a sharply pointed tegular edge opposite the median apophysis (fig. 25); females also closely resemble those of *A. sober* but have a narrower epigynal septum and less anteriorly restricted lateral epigynal margins (fig. 27).

MALE: Total length 7.4. Coloration as in *A. sober*. Leg spination: femora: II p1-2-1; IV r0-0-2; tibiae: I d0-0-1, r0-1-0; II d1-0-1, r0-1-0; III, IV d1-1-1; metatarsi: I, II p1-1-0, r1-1-0; III p1-2-2, r1-2-2; IV p1-2-2, r1-1-2. Tegulum widened opposite median apophysis, with pointed edge (fig. 25); dorsal prong of retrolateral tibial apophysis reduced to tiny, sharp point tip (fig. 26).

FEMALE: Total length 9.7. Coloration as in *A. sober*. Leg spination: femora I r1-1-1; tibiae: II r0-1-0; III, IV d1-1-1; metatarsi III, IV p1-2-2. Epigynum with median septum widened at about half its length, lateral margins longer than widened portion of septum (fig. 27); spermathecal bulbs rounded (fig. 28).

OTHER MATERIAL EXAMINED: CALIFORNIA: **Alameda Co.:** Berkeley, (AMNH), 4 ♂, 2 ♀.

Map 1. Western North America, showing records of *Anachemmis sober* (open circles), *A. linsdalei* (filled circles), *A. jungi* (filled squares), *A. aalbui* (open square), and *A. beattyi* (triangles).

Chamberlin, AMNH), 1 ♀. **Santa Cruz Co.:** Santa Cruz, Apr. 7, 1979 (D. Boe, UCR), 2 ♂, 1 ♀.

DISTRIBUTION: Northern and central California (map 1).

NATURAL HISTORY: Collection records of *Anachemmis linsdalei* are from elevations of 100 to 500 m and predominantly from various types of oak woodlands, but also from pine and redwood forests. This species occurs on ground habitats and has been collected under rocks, logs, in and on litter, in *Neotoma* nests, in houses, and on roads at night. Hand collected specimens (about 200) show a similar abundance to *A. sober*, being collected year round with females being slightly more common and a peak of activity from April to June (chart 2). The 450 specimens obtained from ethylene glycol pitfall traps (10 traps) at Arroyo Seco, Monterey County, indicate a much higher proportion of males (chart 3). During periods of peak activity, this species was, by far, the most abundant spider in the pitfall traps.

Anachemmis jungi, new species

Figures 29–32; Map 1

TYPES: Male holotype and female allotype from Titus Canyon Cave, Death Valley National Monument, Inyo Co., California (Jan. 22, 1972; A. Jung), deposited in AMNH.

ETYMOLOGY: The specific name is a patronym in honor of the collector of the types.

DIAGNOSIS: Males of this long-legged, cavernicole species resemble those of *A. aalbei* in having a narrow, erect embolus (fig. 29),

Chart 2. Seasonal abundance of *Anachemmis linsdalei* based upon the total of hand-collected specimens examined (182) from all localities. Y-axis = number of specimens; X-axis = time in months; solid lines = females; dashed lines = males.

but have a much narrower ventral prong of the retrolateral tibial apophysis (fig. 30); females also resemble those of *A. aalbui* in having very short anterolateral epigynal margins, but have the epigynal septum widened at the level of the anterolateral epigynal margins (fig. 31).

MALE: Total length 8.9. Color paler than in *A. sober*, with carapace brownish orange, legs with femora light yellow, grading to brownish orange on more distal segments, abdomen pale white. Leg spination: femora: I p0-2-1; II p2-2-1; IV r0-1-2; tibiae: I, II d1-0-1, v6-4-2, r1-0-0; IV r1-0-1; metatarsi: I, II p1-1-0, r1-1-0; III p1-2-2; IV v2-2-2. Tegulum not widened opposite median apophysis, embolus relatively narrow, erect (fig. 29); dorsal prong of retrolateral tibial apophysis relatively large for genus, ventral prong relatively narrow (fig. 30).

FEMALE: Total length 13.6. Coloration as in male. Leg spination: femora: I p0-3-1; II p2-2-1; III r2-1-1; IV p2-1-2, r0-1-2; tibiae: I, II v4-6-2, r0-1-0; metatarsi: III p1-2-2; IV r1-1-2. Anterolateral epigynal margins and atrium relatively short, septum widened at that level (fig. 31), median epigynal ducts massive (fig. 32).

OTHER MATERIAL EXAMINED: CALIFORNIA: Inyo Co.: Defense Cave, Stone Canyon, Argus Range, Sept. 7, 1988, elev. 4000 ft (R. Aalbu, CAS), 1 ♀; Titus Canyon Cave, Death Valley National Monument, Jan. 22, 1972 (A. Jung, AMNH), 1 ♂.

DISTRIBUTION: Known only from caves in Inyo Co., California (map 1).

Anachemmis aalbui, new species

Figures 33–36; Map 1

TYPE: Male holotype taken in pitfall trap at an elevation of 4300 ft at the Park Headquarters, Mitchell Caverns State Park, San Bernardino Co., California (Mar. 17–June 16, 1979; R. Aalbu), deposited in CAS.

ETYMOLOGY: The specific name is a patronym in honor of the collector of the types.

DIAGNOSIS: Males of this long-legged species resemble those of *A. jungi* in having a narrow, erect embolus (fig. 33), but have a wider ventral prong of the retrolateral tibial apophysis (fig. 34); females also resemble those of *A. jungi* in having very short an-

terolateral epigynal margins, but have the epigynal septum widest anteriorly, rather than at the level of the anterolateral epigynal margins (fig. 35).

MALE: Total length 9.2. Coloration as in *A. jungi*. Leg spination (both legs I missing): femora: II p2-2-1; IV r0-0-2; tibiae II d1-0-1, v4-6-2, r0-1-0; metatarsi: II p2-0-0, r1-0-0; III p1-2-2, r1-2-2; IV r1-1-2. Tegulum not widened opposite median apophysis, embolus relatively narrow, erect (fig. 33); dorsal prong of retrolateral tibial apophysis relatively large for genus, ventral prong relatively wide, especially at base (fig. 34).

FEMALE: Total length 12.3. Coloration as in *A. jungi*. Leg spination: femora: I p0-3-1; II p2-2-1; III r2-1-1; IV r0-0-2; tibiae I, II v4-6-2, r0-1-0; metatarsi: I, II p2-0-0, r2-0-0; III p1-2-2; IV p1-2-2, r1-1-2. Anterolateral epigynal margins and atrium relatively short, septum widened anteriorly (fig. 35), median epigynal ducts massive (fig. 36).

OTHER MATERIAL EXAMINED: CALIFORNIA: San Bernardino Co.: Medicine Cave, Providence

Chart 3. Seasonal abundance of *Anachemmis linsdalei* based upon the specimens collected (450) from 10 pitfall traps maintained at Arroyo Seco, Monterey County, California. Y-axis = number of specimens; X-axis = time; solid lines = females; dashed lines = males.

Mountains State Recreation Area, June 20–Sept. 27, 1988, pitfall (R. Aalbu, CAS), 6♀.

DISTRIBUTION: Known only from San Bernardino Co., California (map 1).

Anachemmis beattyi, new species

Figures 37–40; Map 1

TYPE: Male holotype from Peppersauce Cave Canyon (north side of Santa Catalina Mountains), Pinal Co., Arizona (Apr. 21, 1961; J. Beatty), deposited in AMNH.

ETYMOLOGY: The specific name is a patronym in honor of the collector of the types.

DIAGNOSIS: Males of this distinctive species can be recognized by the distally long and narrowed embolus (fig. 37), females by the anteriorly very wide epigynal septum bearing deep, paramedian invaginations (fig. 39).

MALE: Total length 8.4. Coloration as in *A. jungi*. Leg spination: femora: I p0-3-1, r2-1-2; II p2-1-1; IV r0-1-2; tibiae: I d1-0-1, v4-6-2, r1-1-0; II d1-0-1, v4-6-2, r1-0-0; metatarsi: I r1-0-0; II p0-1-0, r1-1-0. Tegulum not widened opposite median apophysis, embolus narrowed distally (fig. 37); dorsal prong of retrolateral tibial apophysis reduced to tiny point, ventral prong relatively narrow (fig. 38).

FEMALE: Total length 8.8. Coloration as in *A. jungi*. Leg spination: femora: I p0-2-1, r1-1-1; IV p2-0-1, r0-0-2; patellae: III p0-0-0, r0-0-0; IV p0-0-0; tibiae I, II v4-6-2, r0-1-0; metatarsi III p1-2-2. Anterolateral epigynal margins and atrium relatively short, septum much widened at that level, bearing deep paramedian invaginations (fig. 39), median epigynal ducts massive (fig. 40).

OTHER MATERIAL EXAMINED: ARIZONA: **Cocino Co.:** Manzanita Camp, Oak Creek Canyon, July 25, 1952 (M. Cazier, AMNH), 2♀. **Graham Co.:** Lower Canyon, Mount Graham, July 14, 1956 (W. Gertsch, V. Roth, AMNH), 1♀. MEXICO: SONORA: Cajon Bonito, 31°18'N, 108°55'W, Sept. 11, 1973 (V. Roth, CAS), 3♀.

DISTRIBUTION: Known only from Arizona and Sonora (map 1).

ACKNOWLEDGMENTS

We thank all the private collectors listed above, and the following curators of institu-

tional collections, for their help in making specimens available for this revision: Charles Griswold (CAS), Marjorie Moody (CDFA), Brian Brown (LACM), Gonzalo Giribet and Laura Leibensperger (MCZ), Cheryl Barr and Steve Lew (UCB), and Rick Vetter and Tom Prentice (UCR). Mohammad Shadab of the American Museum of Natural History helped greatly with the illustrations. Special thanks go to Wendell Icenogle for his dedicated efforts targeted at resolving the species status of specimens from the San Gabriel Mountains, to Daniel Palmer for donating large samples of southern Californian tenebrionids, and to Wendell Icenogle, Tom Prentice, and Daniel Palmer for helping to sort out relevant specimens from other collections.
