BioOne Complete (complete.BioOne.org) is a full-text database of 200 subscribed and open-access titles in the biological, ecological, and environmental sciences published by nonprofit societies, associations, museums, institutions, and presses.

Your use of this PDF, the BioOne Complete website, and all posted and associated content indicates your acceptance of BioOne's Terms of Use, available at www.bioone.org/terms-of-use.

Usage of BioOne Complete content is strictly limited to personal, educational, and non - commercial use. Commercial inquiries or rights and permissions requests should be directed to the individual publisher as copyright holder.

BioOne sees sustainable scholarly publishing as an inherently collaborative enterprise connecting authors, nonprofit publishers, academic institutions, research libraries, and research funders in the common goal of maximizing access to critical research.

Chapter 3

Preliminary Baseline Survey of the Avifauna of the Nakorotubu Range, Ra and Tailevu Provinces, Fiji.

Alivereti Naikatini and Vilikesa Masibalavu

Team members: Senivalati Vido (Department of Forestry), Sowane Nasemira (Soa village), Mitieli Toakece (Nasau village).

SUMMARY

This report is a preliminary baseline survey of the avifauna of the Nakorotubu Range, Ra-Tailevu Provinces, Viti Levu. The report provides observations and comments on the avifauna observed in the study area.

A total of 38 bird species were recorded in the surveys, fifteen of which were endemic species, four introduced and the remainder native species.

Three globally threatened species for Fiji were recorded – Pink-billed Parrotfinch (Viti Levu endemic), Black-faced Shrikebill and the Friendly Ground-Dove. For birds, the Nakorotubu Range has the same conservation significance as other large forest blocks on Viti Levu.

INTRODUCTION

The Nakorotubu Range is an important forest refuge for Fiji's native flora and fauna covering the whole mountain range that runs along the eastern side of Viti Levu from the Tailevu province in the south up to the province of Ra in the north. It connects to the lowland tropical rainforests of southern and central Viti Levu and also to the dry forests of northern Viti Levu like the Nakauvadra Range. Little bird work has been done in the whole area except a survey that was conducted by Dr Dick Watling around Soa village. The main objectives of this survey were to do a checklist of the bird species of Nakorotubu, look at their abundance and also the presence of Fiji's threatened birds in the area.

Conservation Significance

In the annotated accounts and discussion of the observations, prominence is given to the Conservation Significance of the species concerned. Conservation Significance is based on the following:

- Endemicity Single Island, National, Regional or Regional Near-endemic for those birds
 whose distribution is primarily within the region but which extends to a few islands or an
 island group outside the region.
- Global Threat Status according to the `2008 IUCN Red List of Threatened Species'. The threatened species categories now used in Red Data Books and Red Lists have been in place, with some modification, for over 30 years. Since their introduction these categories have become widely recognised internationally, and the Red List categories provide an easily and widely understood method for highlighting those species under higher extinction risk, so as to focus attention on the need for or efficacy of existing conservation measures. A simplified description of the categories applicable for this guide are as follows (refer http://www.redlist.org for a full description and the annually updated status):
 - CRITICALLY ENDANGERED when a species is facing an extremely high risk of extinction in the wild in the immediate future;
 - ENDANGERED when a species is not Critically Endangered but is facing a very high risk of extinction in the wild in the near future;
 - VULNERABLE a species is Vulnerable when it is not Critically Endangered or Endangered but is facing a high risk of extinction in the wild in the medium-term future;

- NEAR THREATENED is a sub-category of LOWER RISK category, for species which are close to qualifying for Vulnerable; and,
- DATA DEFICIENT there is insufficient information to make an evaluation.

Introduced and naturalised species, some of these species pose a threat to native species and generally increase in abundance as a result of habitat disturbance, especially loss of forest.

National Conservation Status – IUCN's Global Status is used wherever a threatened category has been applied, especially for national endemic species. However, the majority of species in Fiji are resident and breed in other Pacific island countries or even further afield. In such cases the Global Status does not reflect the often differing status in each country, which is very important for the countries concerned. To rectify this, two categories for the conservation status of the Fijian populations of these birds are used.

These follow Watling (2001):

- At Risk the higher category for birds considered to be severely threatened in Fiji;
- Conservation Concern a lower category for birds whose status is known to be declining, under threat or very vulnerable because of small population size, introduced predators or competitors, or adverse land use practices here in Fiji.

METHODS AND STUDY AREA

Study area and base camps

The study area in the Nakorotubu Range is demarcated on Map 6. The team hiked from Matuku village to Base camp 1 (Nabavatu) along the Nabavatu Creek on November 30 and spent three nights there and hiked back to Matuku village on December 3. On December 4 we visited the limestone forests of Nalidi looking for caves and on December 5 hiked from Matuku village to Base camp 2 (Nalalau) on the headwaters of the Lequ Creek which flows down to Nalidi village. We spent two nights at Base camp 2, before hiking back to Matuku village on December 7. The team departed Matuku village for Nasau village on December 7 and spent December 8 surveying the forests around the village. On December 9 the team departed Nasau village for Base camp 3 (Nubunivonu) and spent two nights at Base camp 3 before hiking back to Nasau village on December 11.

Field methods

Bird observations were categorized according to three different observational methods:

- Standardised Transects: Observations during timed transects along paths and river/stream beds – these are then expressed as encounter rates (number of individuals observed divided by number of standardised observer hours (Masibalavu and Dutson 2006);
- 2. Observations during timed periods at an observation post with a 2000 view over the forest;

Incidental observations around the base camps and when hiking between camps.

A summary of the location of the sites surveyed is listed in Table 3.1, and shown in Map 5. A total of 38 hours was spent on bird surveying, 29.25 hours was spent on forest observations, 3.3 hours was spent in 'forest edge – garden' habitats and 5.4 hours in open country (Table 3.2).

RESULTS

Species Recorded

A total of 38 species were recorded in the Nakorotubu Range, primarily in forested habitats but including peripheral open habitats. Fifteen of these are Fijian endemic species (Table 3.3). Three introduced bird species (Common mynah, Jungle mynah and Red-vented bulbul) now considered as invasive were also observed, mainly close to villages and settlements. The Fiji-bush Warbler is the most common species encountered during the survey.

The Pink-billed Parrotfinch (Endangered) one of Viti Levu's most threatened birds, was observed a couple of times in the intact lowland rainforests of Nasau. The other two threatened birds of Viti Levu, the Red-throated Lorikeet (Critically Endangered) and the Long-legged Warbler (Endangered) were not recorded. Two species, the Friendly Ground Dove and the Black-faced Shrikebill that are categorized as Vulnerable, were also recorded.

Four caves visited during the survey had White-rumped swiftlets colonies. The three caves in Nasau had approximately more than 1000 swiftlets in each, whereas the rock overhang near Base camp 1 had about 100 swiftlets.

DISCUSSION

The composition of the birds of Nakorotubu is similar to other large forest blocks on Viti Levu – given the paucity of data (this survey, Watling 2003, Masibalavu 2003, Watling 2008).

No Long-legged warblers were observed despite the healthy state of the native forests. The reason for this could be the lack of running creeks at elevations of more than 300 m above sea level found at other sites like Monasavu, Wabu, and Nakauvadra, where this species was previously recorded (Masibalavu 2004, Masibalavu 2008).

Weather conditions at Base camp 1 and Base camp 2 were drier permitting more work to be done; however, rain was encountered in Base camp 3 which affected the field work. The drier state of the forest in Base camp 1 and Base camp 2 could be a factor affecting the bird composition of this area but this needs follow up work. The vegetation around Base camp 3 is typical lowland tropical rainforest like the Sovi Basin (Naitasiri Province), with a similar bird composition (Masibalavu et. al. 2003, Watling, 2003). The presence of birds like the Pink-billed parrotfinch and Friendly ground dove in the forests of Nasau is noteworthy and would be worth follow up monitoring. Base camp 3,

despite the poor weather, had greater bird activity compared to the two other camps, and this could be attributed to the healthy state of the forest, large forest size and connectivity to other forest systems.

An interesting observation made in this survey was that of the Polynesian starling in Base camp 2. This species is usually rare in forests of Viti Levu; however, we observed this species to be fairly common here moving and foraging in large groups of up to ten individuals. This was observed for the two days we spent at this site. They also showed signs of aggressive behavior towards other species. Whether they were mating or marking out their territory is not clear, but the observation is worthy of a follow up survey.

The presence and abundance of large birds such as Masked-shining parrot and barking pigeon (Table 3.2) in the area can show that both the health and size of the forest is large enough to contain a viable population of birds and other species.

Few trees were observed to be flowering except for some *Bischofia javanica*, *Erythrina* sp., *Garcinia* sp. and *Parinari insularum* which attracted species like White eyes, Slaty monarch, Collared lorry, Wattled honeyeater and Orangebreasted myzomela. However, there were more trees with fruits like *Endorspermum macrophyllum*, *Parinari insularum*, *Callophylum* spp., *Ficus* spp., *Amoraria* sp., *Garcinia* spp., and *Cananga odorata* which attracted birds like the Barking pigeon, Many-colored fruit dove and Golden dove. White-rumped Swiftlets were found nesting during the survey. The three caves visited in Nasau have a good population of this species with each cave having well over 1000 birds. The limestone forests of Nakorotubu were not well covered in this survey and this is noteworthy for future surveys in this area.

Interestingly, not many introduced bird species were encountered during this survey. The majority recorded were mainly near and around villages and settlements. None were observed in any of the camp sites, which show that they have not really been able to spread to these forest areas. However, this should be monitored in the future.

CONCLUSIONS AND CONSERVATION SIGNIFICANCE

The birds of the Nakorotubu Range are similar in composition and approximate abundance, and hence conservation significance, to other large forest blocks on Viti Levu. Further surveys are required to determine the presence/ absence of rare species such as the Long-legged Warbler and the Red-throated Lorikeet. Being an important refuge for birds and the fact that it is connected to other large forest blocks, there is a need to set aside some portions of the Nakorotubu Range as permanent reserves. Future surveys are needed and monitoring program in place for the birds of Nakorotubu. The site could qualify to be one of Fiji's Important Bird Areas (IBA's) due to the presence and abundance of some of Fiji's threatened birds.
