BioOne Complete (complete.BioOne.org) is a full-text database of 200 subscribed and open-access titles in the biological, ecological, and environmental sciences published by nonprofit societies, associations, museums, institutions, and presses.

Your use of this PDF, the BioOne Complete website, and all posted and associated content indicates your acceptance of BioOne's Terms of Use, available at www.bioone.org/terms-of-use.

Usage of BioOne Complete content is strictly limited to personal, educational, and non - commercial use. Commercial inquiries or rights and permissions requests should be directed to the individual publisher as copyright holder.

BioOne sees sustainable scholarly publishing as an inherently collaborative enterprise connecting authors, nonprofit publishers, academic institutions, research libraries, and research funders in the common goal of maximizing access to critical research.

The Pyrrhocoroidea (Hemiptera – Heteroptera) of the Ethiopian region

I.A.D. Robertson

P.O Box 162, Malindi, Kenya

Received 16 July 2002, Accepted 21 October 2002, Published 14 May 2004

The superfamily Pyrrhocoroidea Southwood 1956 is closely related to the Lygaeoidea and the Coreoidea, and was placed by many authors as a subfamily of the Lygaeidae. It was recognized as a separate family by Amyot and Serville in 1843 under the name ‘Cecigenes’ and they divided it into two groups ‘Pyrrhocorides’ and ‘Largides’. These two names became recognized as subfamilies of the Pyrrhocoridae, the family name being established by Fieber (1861). Hussey (1929) quotes Van Duzee (1916), who established the name Euryophthalminae to replace Larginae and divided that subfamily into two tribes Euryophthalmini and Physopeltini. This nomenclature was dealt with in detail by China (1954) who established that Larginae is still the correct subfamily name. Van Duzee’s tribe Euryophthalmini is confined to American genera. China (1954) states that because of their differing affinities, the Larginae being more closely related to the Lygaeidae and the Pyrrhocorinae to the Coreidae, both these subfamilies should assume family status. This change in status was followed by China and Miller (1959). Southwood (1956), following a study of the eggs of the Heteroptera, had also suggested that the families Largidae and Pyrrhocoridae together formed the superfamily Pyrrhocoroidea. This view was accepted and confirmed by Schaefer (1964) following detailed morphological investigations of representatives of the Lygaeoidea, Coreoidea and Pyrrhocoroidea. Schaefer also summarised the conclusions of other workers who had undertaken comparative studies of morphological characters within the three superfamilies.

China and Miller (1959) used the following characters to typify the Pyrrhocoroidea:

1. Abdominal trichobothria present
2. Scutellum small, shorter than the clavus, a distinct claval commisure present
3. Antennophores visible from above
4. Antennae four segmented
5. Ocelli absent
6. Membrane of the hemelytra usually with two basal cells, from which 7 - 8 branching longitudinal veins extend to the apical margin
7. Medium to large, brightly colored, usually phytophagous bugs

Only 13 out of the 18 genera now recognised in the Ethiopian Region can be said to be brightly colored; the other five genera being dark in general coloration. The two families are: Largidae - Sixth visible (seventh actual) ventral abdominal segment in the female cleft in the middle; Pyrrhocoridae -Sixth visible ventral abdominal segment entire in both sexes. There does not seem to be any way to key out the males of the African Largidae (Physopelta) without dissection.

Hussey (1929) lists 360 species worldwide in the superfamily Pyrrhocoroidea Southwood 1956 with 77 African species, in 13 genera, the genus *Dysdercus* containing 15 of these species. Since then, a number of new species have been described. This catalogue is based on the literature up to 2000 and the study of material in the National Museum of Kenya (NMK), Nairobi, which includes my own collections from east Africa, mainly Tanzania. The present check-list gives 102 species in 18 genera.

The literature contains few references to the biology and ecology of the superfamily, being largely taxonomic. Only the genus *Dysdercus*, containing the ‘cotton stainers’ is of economic importance, and for that genus the literature is very extensive. For this reason the genus *Dysdercus* and the literature pertaining to it has been excluded from the present paper, except that, for completeness, it has been included in the list of species and the key to genera. Some of the other genera in the superfamily must be regarded as rare, few specimens being available in collections and in some, descriptions have been done on the basis of one or two specimens, sometimes only a single sex being known. Madagascar has been considered as being outside the scope of this work, as have the Mascarene Islands.

KEY TO THE AFRICAN GENERA

The first key to separate the African genera was by Stål (1865). The next key specifically intended for genera in the Ethiopian Region was by Villiers and Dekeyser (1951), to allow placement of their newly described genus *Sicnatus*. The characters used by Stål (1865) and Villiers and Dekeyser (1951) are similar. The present key has been altered from theirs only to accommodate recently described genera. It is expected to be accurate only within the Ethiopian Region. Much information has been published in recent years on the detailed structure of the male and female genitalia, differences that are particularly useful in the determination of species, and which are quite diagnostic for some genera, for example, the crossed parameres of the genus *Cenaeus*. So far, however, less than half the species have been adequately studied and generic keys based on these characters should wait until knowledge is more complete.

1. Sixth visible abdominal segment in the female cleft longitudinally, entire in the male. Medium to large insects (10 - 16 mm). General color red and black (Family Largidae).

PHYSOELTA

- Sixth visible abdominal segment entire in both sexes (Family Pyrrhocoridae).

2

2. Form exceedingly ant-like. Smaller insects (6 - 8 mm). General color black, or black and red. Mostly brachypterous, but macropterous individuals known.

MYRMOPLASTA

- Form not exceedingly ant like, at least not in the adult. Most genera macropterous

3

- 3 Head strongly bent down in front of the eyes. Medium sized insects (8 - 11 mm). Brightly colored. Brachypterous.

SIANGO

- Head not strongly bent down in front of the eyes. Various sizes and colors. Usually not brachypterous.

4

- 4 Head transversely narrowed and depressed behind the eyes. Larger insects (14 - 17 mm). General color red and black.

ANTILOCHUS

- Head not as above, usually more or less horizontal.

5

- 5 Apex of corium acute. Larger brighter colored insects, (12 - 20 mm). General color black and red or brown. The ‘cotton stainers’. Venter usually with contrasting stripes.

DYSDERCUS

- Apex of corium rounded. Other characters different.

6

- 6 Apical borders of third and fourth visible sternites straight, not sinuate laterally. Rostrum very long. Large insects, (25 - 32 mm). General color reddish and black.

CALLIBAPHUS

- Apical borders of third and fourth visible sternites sinuate laterally. Usually without a very long rostrum.

7

- 7 Apex of corium much longer than the corial-claval suture. Large slender insects, (18 - 24 mm). General color red and black.

ROSCIUS

- Apex of the corium subequal to the corial-claval suture. .

8

- 8 Anterior discal area of pronotum not limited laterally by a furrow. Medium to large sized insects, (10 - 23 mm). General color ochre to brownish.

ODONTOPOUS

- Anterior discal area of pronotum limited by a clear lateral furrow, sometimes punctate, at least towards the front.

9

9. Anterior discal area of pronotum circumscribed by an impressed continuous furrow. Borders of pronotum convex and regularly curved at anterior and posterior angles. Body often hairy. Medium sized insects, (8 - 14 mm). General color red and black, or brownish.

SERICOCORIS

- Anterior and posterior discal areas of pronotum separated by a furrow, which may or may not be punctate. Borders of the pronotum more or less concave at the middle.

10

10. Anterior and posterior discal areas of pronotum separated by a furrow which is not punctate. Eyes sessile. Body never hairy. Insects of medium size, (7 - 14 mm). General color black, red and brownish.

NEODINDYMUS

- Pronotum not as above. Other characters different.

11

11. Anterior and posterior discs of pronotum of different textures and colors separated by a row of punctures. Eyes more or less prominent, not sessile. Smaller oval insects, (7 - 14 mm). General color ochre or brownish. Some species brachypterous.

CENAEUS

- Pronotum not as above. Eyes sessile.

12

12. Anterior discal area of pronotum clearly limited by a deeply punctate furrow. The first segment of the rostrum thick, not longer than the head. Larger insects, (15 mm). General color black and reddish or cream.

GROMIERUS

- First segment of rostrum not thick. Anterior discal area of pronotum not as above.

13

13. The first segment of rostrum equal to half the length of the head. Small species, (7 - 10 mm). General color black, with some red. Majority brachypterous.

SCANTIUS

- First segment of rostrum not as above, sometimes exceeding the length of the head.

14

14. First segment of rostrum reaching the apex of the prosternum. Antennae with many bristles. Front femora swollen and the front tibiae curved. Small insects, (6 - 8 mm). General color blackish. Mostly brachypterous.

ADERRHIS

- First segment of rostrum not as above. Antennae without many bristles.

15

15. Third segment of antennae thickened, much bulkier than the fourth. Small insects, (6 - 9 mm). General color dark brown or black. Brachypterous.

DERMATINUS

- Antennae not of this form.

16

16. Fourth segment of antennae strongly thickened in the middle. Small insects, (6 mm). General color black. Brachypterous.

NEOINDRA

- Antennae not of this form. Color not wholly black.

17

17. First segment of antennae longer than the second. Anterior disc of pronotum limited anteriorly and posteriorly by distinct punctures. Medium sized insects, (8 - 12 mm). General color black and orangish. Mostly brachypterous.

SCHMITZIANA

- First segment of antennae shorter than the second. Apex of first segment of rostrum does not reach prosternum. Smallish insects, (8 mm). General color black and reddish.

SICNATUS

FAMILY LARGIDAE

The family Largidae was established by Amyot and Serville (1843), under the name Largides, which can be regarded as a valid group name based on the generic name *Largus* Hahn 1831 (China 1954). It is represented in Africa only by three species in the large genus *Physopelta* Amyot and Serville 1843. The last generic description was by Stål (1865) and was done before all the African species had been described. Some of the detailed characters given by Stål, therefore, do not fit the African species too well. For example the description of the antennae only holds good for *Physopelta festiva* (Fabricius 1803).

PHYSOPELTA Amyot & Serville 1843

Type species: *Physopelta erythrocephala* Amyot & Serville 1843. (=*Physopelta albofasciata* (De Geer 1773) Designated by Distant (1903) and quoted as a logotype by (Hussey 1929)

Country of origin of type species: Java

Type depository: not known

KEY TO THE AFRICAN SPECIES MODIFIED FROM LESTON (1969)

1. Head plus body length more than 15 mm. Corium with a black band. Side of the abdomen red, with black lines of varying width anteriorly on each segment. Anal segment black.

Physopelta festiva (Fabricius 1803)

- Head plus body length less than 15 mm.

2

2. Corium with a black spot. Pronotum with the front half orange. Side of the abdomen reddish with the last two segments black. (12 - 13 mm).

Physopelta analis (Signoret 1858)

- Corium with a nearly complete black band. Pronotum with the frontal half pitchy-black. Side of the abdomen wholly black (10 - 12 mm).

Physopelta melanoptera Distant 1904

Physopelta analis (Signoret 1858)

Type depository: Vienna: Naturhistoriches Museum

Country of origin of type: Nigeria (Old Calabar)

Distribution: Cameroon (Barombi); Gabon; Ghana (Addah); ‘Guinea’; Ivory Coast; Nigeria (Old Calabar)

Measurements: length 12-13mm; width 4-5mm (1 male)

Collected in Tanzania October-May. In West Africa associated with *Mallotus oppositifolius* (Euphorbiaceae) (Leston, 1969; Duviard, 1974).

FAMILY PYRRHOCORIDAE

ANTILOCHUS Stål 1863

This is a large genus, mainly found in the Oriental and Australasian Regions. Three species are recorded from the Ethiopian region by Hussey (1929) but on examination of material in the National Museum of Kenya it was found that the third species, *Antilocus violaceus* Carlini 1892, is not a member of this genus at all, but definitely belongs to the genus *Odontopus* Laporte. An unnamed specimen of *Odontopus* in the NMK collection, from Somalia, matches Carlini's description very closely. Consequently, only two species of the Genus *Antilocus* are present in the Ethiopian Region, one is West African, the other is confined to Eastern and Southern Africa.

Type species: *Antilocus coqueberti* (Fabricius 1803) quoted as type species by Distant (1904) and as a logotype by Hussey (1929)

Country of origin of type species: India

Type depository: not known

Synonyms: *Neaeretus* Reuter 1887

Illustrations: see *Antilocus boerhaviae*

<i>Antilocus</i> Stål 1863	Stål 1863: 393
<i>Antilocus</i> Stål	Stål 1866: 3 and 4
<i>Antilocus</i> Stål	Stål 1870: 101 and 103
<i>Odontopus</i> De Lap.	Walker 1872: 174
<i>Neaeretus</i> Reuter 1887	Reuter 1887: 92
<i>Antilocus</i> Stål	Lethierry and Severin 1894: 243
<i>Antilocus</i> Stål	Bergroth 1894a: 358
<i>Antilocus</i> Stål	Breddin 1901: 175
<i>Antilocus</i> Stål	Kirkaldy and Edwards 1902: 166
<i>Antilocus</i> Stål	Distant 1904: 100
<i>Antilocus</i> Stål	Hussey 1929: 36
<i>Antilocus</i> Stål	Schmidt 1932: 236

The two species of *Antilocus* can easily be separated by the very different appearance of the pronotum and elytra:

1. Pronotum black, surrounded by a continuous narrow yellow band. Elytra black with irregular narrow yellowish bands that appear to enclose a large irregular black spot. Sides of the thorax predominantly black. Sides of the abdomen red, with narrow whitish lines anteriorly on each segment. The whitish lines vary in thickness and there may be some black coloration towards the rear of the abdomen. Anal segment, red.

Antilocus boerhaviae (Fabricius 1794)

2. Pronotum black, the borders reddish-orange with the red color being wider at the posterior corners. The elytra black with reddish patches separated to leave a central area in the form of a black cross. The pattern is rather variable, but distinctly different from *Antilocus boerhaviae*. Sides of the thorax reddish, sometimes darker. Sides of the abdomen red with whitish lines on the anterior of each segment, which vary somewhat in thickness. No black coloring is present. Anal segment, red.

Antilocus nigrocruciatus Stål 1855

Antilocus boerhaviae (Fabricius 1794)

Type depository: not known

Country of origin of type: 'Guinea'

Distribution: British East Africa; Cameroon; Congo (Brazzaville); Democratic Republic of Congo; Gabon; 'Guinea'; Nigeria; Senegal; Sudan

Synonyms: *Antilocus submaculatus* Kirkby 1896

Measurements: length, male 15.5 mm (1); female 18.2 mm (1)

<i>Lygaeus boerhaviae</i> Fabricius 1794	Fabricius 1794: 152
<i>Lygaeus boerhaviae</i> Fabricius	Fabricius 1803: 220
<i>Antilocus boerhaviae</i> Fabr.	Stål 1866: 4

<i>Antilocus boerhaviae</i> Fabr.	Stål 1868: 81
<i>Antilocus boerhaviae</i> Fabr.	Stål 1870: 104
<i>Odontopus boerhaviae</i> Fabr.	Walker 1872: 176
<i>Antilocus boerhaviae</i> Fabricius	Lethierry and Severin 1894: 343
<i>Antilocus boerhaviae</i> (F.)	Karsch 1894: 106
<i>Antilocus submaculatus</i> Kirby 1896	Kirby 1896: 268
<i>Antilocus boerhaviae</i> Fabr.	Distant 1902b: 36
<i>Antilocus boerhaviae</i> Fabr.	Distant 1902b: 36
<i>Antilocus boerhaviae</i> (Fabr.)	Kirkaldy and Edwards 1902: 172
<i>Antilocus boerhaviae</i> Fabricius	Courteaux 1922: 285
<i>Antilocus boerhaviae</i> (Fabricius)	Hussey 1929: 37
<i>Antilocus boerhaviae</i> F.	Blöte 1931: 102

<i>Antilocus nigrocruciatus</i> St.	Mancini 1961: 31

CALLIBAPHUS Stål 1868

The genus *Callibaphus* (Stål 1868) is confined to the Ethiopian Region and only three species have been described. These insects are very large and are rare in collections. Distribution is very much West African in published papers, reaching as far east as Uganda. Bergroth (1906) described a third species *Callibaphus gigas* from the Comoro Islands which are outside the Ethiopian Region, but it is included because Bergroth himself indicated that he thought his specimen to be conspecific with *Callibaphus longirostris* (Drury 1782). *C. gigas* has never formally been synonymised, probably because of the great gap between its location and those of all the other published records. The type would have to be examined before a decision could be reached.

Type species: *Callibaphus longirostris* (Drury 1782). Quoted as a monotype by Hussey 1929

Country of origin of type species: Sierra Leone

Type depository: London: Natural History Museum

Illustrations: see *Callibaphus longirostris*

<i>Roscius</i> (<i>Callibaphus</i>) Stål 1868	Stål 1868: 82	description

Callibaphus Stål
Callibaphus Stål

Lethierry and Severin 1894: 245
Hussey 1929: 50
Schmidt 1932: 246

The two African species may be separated quite easily, although the black markings both species bear on the pronotum and elytra are quite similar and are not useful as characters for separating the species:

1. Head dark red with a longitudinal black mark between and behind the eyes. Color above dark red, dull, with little variation among the available specimens. Membrane translucent. Sides of the thorax black, with dark red stripes at the rear of each segment. Sides of the abdomen dark red with black bands of varying width at the anterior of each segment, the black becoming dominant on the last two segments. Color changes diffuse. Anal segment dark red.

Callibaphus albipennis Distant 1914

2. Head orange to red without any black markings. Color above bright orange to red. Membrane black. Sides of thorax and abdomen black, with yellow lines of varying width at the rear of each segment. Color changes sharply defined. Anal segment orange to red.

Callibaphus longirostris (Drury 1782)

Callibaphus albipennis Distant 1914

Type depository: London: Natural History Museum

Country of origin of type: Uganda

Distribution: Kenya; Uganda

Measurements: length, male 26.9 mm(1); female 31.7 mm (1)

Linnauvori 1988: 13

Earlier data indicate that this species is confined to West Africa, Cameroon and Congo (Brazzaville). Bergroth (1906) described *C. gigas*

from the Comoro Islands and indicated that it seemed very likely to be a variety of *C. longirostris*. A record from Tanzania in the National Museum of Kenya provides a possible link between the very widely separated populations in West Africa and the Comoro Islands.

***ROSCIUS* Stål 1866**

The genus *Roscius* is confined to the Ethiopian region and five species have been described. The genus is characterized by the fact that the apical border of the corium is much longer than the commissure of the corium-clavus. This character reflects the slender elongate shape of all the species in the genus.

Type species: *Roscius elongatus* (Schaum 1853)

Country of origin of type species: Mozambique

Type depository: not known

Illustrations: see *Roscius circumdatus* and *Roscius illustris*

Roscius Stål 1866 Stål 1866: 8

Roscius Stål Stål 1870: 102

Roscius Stål Walker 1872: 173

Roscius Stål Lethierry and Severin 1894: 245

Roscius Stål Hussey 1929: 51

Roscius Stål Schmidt 1932: 246

Five species are described in the published literature, although the status of *Roscius elongatus* and *Roscius quadriplagiatus*, both originally described by Schaum in 1853, is doubtful. As no authentic specimen of *Roscius elongatus* (Schaum 1853) is available it has been left out of the key below.

1. Head red without any black markings. Front half of the pronotum raised, black, separated from the rear half by a marked impressed furrow which curves backwards to the sides. The front half of the pronotum having no yellow, or having only a very narrow line of yellow on the anterior edge, which may be reduced to two yellow lateral anterior spots. The elytra with the anterior yellow marking sub-triangular, not an irregular shape. Sides of the abdomen with the first two visible segments markedly yellow or pale, the next two almost wholly black. Anal segment red.

Roscius illustris Gerstaecker 1873

- Head red, but having at least some black markings between and behind the eyes

2

2. Pronotum wholly surrounded by a narrow yellow border. The elytra with narrow elongate yellowish markings, the rear pair forming a border between the corium and the membrane.

Roscius circumdatus Distant 1881

- Pronotum not as above. Markings on the elytra and the sides of the abdomen different.

3

3. Pronotum flattened, with a marked wide orange anterior border and wide lateral orange borders. At most a very narrow band of orange posteriorly. The elytra with the anterior orange spots not triangular, but elongate and irregular, reaching to the shoulder. Sides of the abdomen much like *Roscius illustris*, but the first two visible segments red, with black coloration towards the connexivum, the next two segments almost wholly black. Anal segment red.

Roscius guilielmi Bergroth 1926

- Pronotum raised and divided by a curved furrow, but the yellow markings usually form a border on all four sides, narrowest and sometimes missing on the anterior half, laterally. Always with a yellow anterior border. The yellow markings being broadest at the posterior lateral corners. The elytra with the anterior yellow markings not triangular, irregular and extending forwards to the shoulder. Sides of the abdomen red, with black lines anteriorly on each segment. The width of the black varies, but the stripes are widest on the third and fourth visible abdominal segments. Anal segment red.

Roscius quadriplagiatus (Schaum 1853)

Roscius elongatus (Schaum 1853)

Type depository: not known

Country of origin of type: Mozambique

Distribution: Angola; Congo (Brazzaville); Gabon; Mozambique; Tanzania; Zanzibar

Measurements: length 24 mm, width 8 mm (ex. Lit.)

<i>Pyrrhocoris elongatus</i> Schaum 1853	Schaum 1853: 358	description
<i>Pyrrhocoris elongatus</i> Schaum	Schaum 1862: 46	description
<i>Roscius elongatus</i> Schaum	Stål 1866: 8	description
<i>Roscius elongatus</i> Schaum	Stål 1870: 109	
<i>Roscius elongatus</i> Schaum	Walker 1872: 173

<i>Roscius elongatus</i> Schaum	Schmidt 1932: 247	
<i>Roscius elongatus</i> Schaum	Villiers 1967: 372	

This species is widely distributed in southern and eastern Africa. It seems to be very closely related to *Roscius quadriplagiatus* (Schaum 1853) according to the written descriptions (Schaum 1853, repeated in 1862): *Pyrrhocoris quadriplagiatus* Schaum; Supra niger, capite thoracisque marginibus rufus, elytrorum maculis duabus flavis, subtus rufus, pectoris lateribus antennis pedibusque nigris. Long 8 lin (= 16.8 mm). *Pyrrhocoris elongatus* Schaum; Supra niger, epistomate, thoracis margine antico et postico, elytrorum maculis duabus rufis, anteriori sublunata, subtus rufus, pectoris lateribus pedibusque nigris. Long 10 lin (= 21.0 mm).

Roscius guilielmi Bergroth 1926

Type depository: not known

Country of origin of type: Democratic Republic of Congo

Distribution: Congo (Brazzaville); Democratic Republic of Congo; Guinea; Uganda

Measurements: length, male 17.0 mm (1); female 20.0 mm (1)

<i>Roscius guilielmi</i> Bergroth 1926	Bergroth 1926: 11	description
<i>Roscius guilielmi</i> Bergroth	Hussey 1929: 52	
<i>Roscius guilielmi</i> Bergroth	Villiers 1953: 298	
<i>Roscius guilielmi</i> Bergroth	Villiers 1967: 372	

This species has a West African distribution, and specimens in the NMK collection from western Uganda probably reflect the eastern limit of its range.

Roscius illustris Gerstäcker 1873

Type depository: Berlin Museum

Country of origin of type: Kenya

Distribution: Kenya; Mozambique; Tanzania; Zanzibar

Measurements: average length, male 14.4 mm (6), female 18.3 mm (7)

<i>Roscius illustris</i> Gerstäcker 1873	Gerstäcker 1873: 414	description, illustration
<i>Roscius illustris</i> Gerst.	Gerstäcker 1892: 50

ODONTOPUS Laporte 1832

Hussey (1929) listed fifteen species in this genus, of which only six occurred in the Ethiopian Region. Since Hussey's catalogue was published two more species and one new variety have been described from the Ethiopian Region. All the members of the genus have a very similar appearance and all seem to be associated with the plant families Sterculiaceae and Malvaceae.

In 1904 Kirkaldy proposed the name *Probergrothius* for this genus as a replacement for *Odontopus* Laporte 1832, on the grounds that the name was preoccupied by a genus of Coleoptera, described by Siebermann. The details of priority had already been established by Alluaud (1889) fifteen years before Kirkaldy made his proposal. Kirkaldy himself realised that the name *Odontopus* was not validly preoccupied (Kirkaldy 1905), and this view was supported by Distant (1919). Only Hesse (1925) accepted the new name. However, Stehlík (1966) renewed the claim that *Odontopus* Laporte 1832 is preoccupied by a genus of Coleoptera described under the name *Odontopus* by Say (1831). Stehlík therefore proposes that the name *Probergrothius* Kirkaldy 1904 be reinstated for the Ethiopian and Oriental species in the genus (the Madagascan species having been transferred to a new genus). In this work, the name *Odontopus* is retained in the hope that the renaming of this large genus will be referred to the International Commission on Zoological Nomenclature for their consideration.

Type species: *Odontopus sexpunctatus* Laporte 1832. Quoted as a monotype by Hussey 1929

Country of origin of type species: Senegal

Type depository: not known.

Synonyms: *Probergrothius* Kirkaldy 1904

KEY TO THE AFRICAN SPECIES

Odontopus angolensis Distant 1902 and *Odontopus obscurellus* Blöte 1933, which is only known from Zimbabwe, are not included because I have not seen specimens.

1. Larger species (16 - 23 mm) with one pair of large black rounded spots posteriorly on the elytra. (A variety, *O. notabilis* var. *kambovensis* lacks the black spots). Body mainly unicolorous, ochraceus. Antennae with the first segment red and the other three segments dark. Pronotum with the frontal part limited by two fairly deeply impressed black lines. Scutellum black. Thorax with the sterna black. Abdomen with the incisures marked with narrow blackish lines.

Odontopus notabilis Distant 1902

- Elytra not showing this pattern. Pronotum and other body parts different. 2

2. Large species (16.0 mm) with the elytra having one pair of round black spots posteriorly and a pair of black bands anteriorly. Head whitish. Pronotum with the frontal area whitish. Scutellum the same color as the elytra. Membrane milky. Thorax with the sterna whitish. Sides of the abdomen whitish ventrally, but darkening in the dorsal half.

Antilocerus violaceus (Carlini 1892)
(See discussion of *Antilocerus*)

- Elytra not having this pattern. Body colors different. 3

3. Species with not more than two pairs of small spots on the elytra. Sometimes the anterior pair are very small or missing. 4

- Species with three pairs of spots on the elytra, sometimes the two anterior pairs are partially joined. 6

4. Species (14 - 20 mm) markedly unicolorous, ochraceus, without red legs. At most narrow reddish stripes marking the abdominal incisures. Head quite pale, ochraceus. Frontal area of the pronotum limited by two dark lines. Last two segments of the antennae dark.

Odontopus modestus Distant 1902

- Species with red legs and generally much brighter coloring than the above. 5

5. Species (16 mm) with the central lobe of the head having a longitudinal black stripe running the whole length of the head. Head, other than the central black longitudinal stripe, orange. Pronotum with a pale anterior collar, the frontal area orange, limited by two distinct black lines. Scutellum orange. Membrane darker than the elytra. Antennae dark red, getting darker towards the tip. Legs red. Thorax with the sterna reddish with dark borders, sometimes all darker. Sides of the abdomen reddish, with wide blackish bands of variable width at the anterior of each segment.

Odontopus exsanguis (Gerstäcker 1892)

- Species (14 - 17 mm) with the central lobe of the head with a red longitudinal stripe running the whole length of the head. Head, other than the central red longitudinal stripe, ochraceus. Pronotum with a pale anterior collar and the frontal area ochraceus, sometimes darker shaded, bounded by two marked black lines. Antennae red, third and fourth segments darker. Legs reddish. Thorax with the sterna dark reddish. Membrane much the same color as the elytra. Sides of the abdomen yellowish, with broad but regular black stripes anteriorly on each segment.

Odontopus confusus Distant 1902

6. Species (14 - 21 mm) occurring in two color forms, red and black, but in both cases the elytra with two pairs of smallish spots anteriorly (rather larger and partially joined together in the black form) and a single pair of larger spots posteriorly. Details of the black color form. Body color ochraceus. Head with a central black area at the rear, tylus red. Pronotum with the frontal area black. Scutellum black. Elytra with the black spots arranged as in the illustration. Thorax with the sterna black. Abdomen with the sides reddish-yellow, and with black stripes anteriorly on each segment.
Details of the red color form. Body ochraceus with a reddish tinge. Head with the rear central area and the tylus red. Pronotum with the frontal area red, but limited by black lines. Scutellum red or blackish red. Elytra with the black spots arranged as in the illustration. Thorax with the sterna black. Abdomen with the sides reddish-yellow, more strongly diffused with red ventrally, and black stripes anteriorly on every segment.

Odontopus sexpunctatus Laporte 1832

- Species (15 - 18 mm) with two pairs of small separate black spots anteriorly on the elytra. A single pair of small black spots posteriorly.

Odontopus notabilis Distant 1902 var. *kambovensis* Goursat 1931

This variety of *O. notabilis* was described by Goursat 1931 from a specimen originating in Kambove (Democratic Republic of Congo, Shaba). The main difference between it and the nominate form is that it lacks the distinct rounded black spot at the apex of the corium.

This variety is well represented in the National Museums of Kenya collection and the specimens come from two of the same localities in

western Tanzania as did the nominate species, obviously part of the same collections.

Measurements: average length, male 16.7 mm (8), female 21.0 mm (5)

<i>Probergrothius sexpunctatus</i> (Laporte de Castelnau)	Linnauvori 1988: 16	

This species is very widespread in the Ethiopian Region. There are two distinct forms, one with a blackish appearance, the other being reddish, although in both the spots on the corium are black. The reddish form is the one originally described by Laporte de Castelnau in 1832, from Senegal, and his illustration (Plate IX, Figs. 5 and 5a) shows two separate spots near the base of each corium; in this form the anterior area of the pronotum is red. It is also illustrated by Stehlík 1966b (Plates III and IV). The other form, illustrated in Guerin-Meneville (1847-51, Plate 6, Fig. 6) and referred to in the caption as *Astemma percheroni*, shows the two basal spots on the corium coalesced into a single transverse spot, retaining the single spot near the apex of the corium. In this form the anterior area of the pronotum is black. The NMK collection has specimens of the black form from Kenya, Sudan and Uganda and the red form from Tanzania.

SERICOCORIS Karsch 1892

This genus, first described by Karsch (1892) and based on hairy insects collected in Cameroon, was revised by Stehlík in 1965. Stehlík's treatment of the genus concentrated on the use of the details of the male and female genitalia to determine species and this represented a major advance in the knowledge of the taxonomy of the superfamily.

Hussey 1929 listed only two species in the genus, but following Stehlík 1965a the number now stands at fourteen. Only one of these is a new species, *Sericocoris obuduanus* Linnauvori 1988. The rest have been transferred, by Stehlík 1965a, from other genera on the basis of detailed study of the genitalia. The genus is confined to the Ethiopian Region and the species are mostly rare in collections. Little is recorded in the published literature about the ecology of the species, although from the distribution and localities in which they have been found, they are most likely to be associated with forest habitats. Five of the fourteen species in the genus have been recorded as occurring in Eastern Africa, including Rwanda; the rest are West African, with Democratic Republic of Congo being the most easterly country.

In a large genus such as this, when many species are not available for study, the older written published descriptions have been found to be inadequate. The problem is mainly that authors have not followed a standard pattern of description and one is often left wondering about what has been left out. This lack is emphasized by the detailed and well illustrated paper of Stehlík 1965a.

Type species: *Sericocoris acromelanthes* Karsch 1892. Quoted as a monotype by Hussey 1929

Country of origin of type species: Cameroon

Stehlik divided the genus into three subgenera depending on the degree of hairiness of the species:

Sericocoris, hairy

Sericocoriopsis, dorsal surface of the body almost hairless, but some pubescence on the ventral surface. This character seems quite variable.

Pseudocenaeus, hairless. This subgenus contains species that are smaller and more slender than the two subgenera noted above.

MYRMOPLASTA Gerstäcker 1892

The species in this genus are ant-like. In this they differ from all the other genera of the Ethiopian Pyrrhocoroidea. All the species have a short rounded abdomen, which is strongly rounded below and with the upper surface rounded to some extent, with the thorax extended and restricted giving the appearance of a petiole. The genus is restricted to Eastern Africa, the most westerly record being in Democratic Republic of Congo.

Type species: *Myrmoplasma mira* Gerstäcker 1892

Country of origin of type species: Tanzania

Type depository: not known

description, illustration

description, illustration

description, illustration

This species exhibits sexual dimorphism, the abdomen of the male being mostly black, while that of the female is striped black and yellow. The species is probably synonymous with *M. vittiventris* (see below). It is also recorded that the species may be brachypterous, the most common condition, or macropterous.

***Myrmoplasta vittiventris* Carlini 1894**

Type depository: Genoa Museum

Country of origin of type: Uganda

Distribution: Uganda

Measurements: length 8 mm, width 3.5 mm (female) (ex. Lit.)

<i>Myrmoplasta vittiventris</i> Carlini 1894	Carlini 1894: 471	description
<i>Myrmoplasta vittiventris</i> Carl.	Bergroth 1913a: 167	
<i>Myrmoplasta vittiventris</i> Carlini	Hussey 1929: 70	

Carlini described the species from a single female specimen. Comparing the texts of Carlini (1894) and Martin (1900) indicates that *Myrmoplasta vittiventris* Carlini 1894 and *Myrmoplasta potteri* Martin 1900 are one species although this cannot be resolved without examination of the type specimens. This, if correct, would then give *Myrmoplasta vittiventris* Carlini 1894 the priority.

SCHMITZIANA Stehlik 1977

The genus has three species, all of which are very rare, and is distributed very widely. The type species, *Schmitziana pilosa* Stehlik 1977 comes from South Africa (Transvaal) and is only known in a brachypterous form. *Schmitziana polymorpha* Stehlik 1977 comes from Democratic Republic of Congo (Upemba N.P.) and is known in both brachypterous and macropterous forms. *Schmitziana grandis* (Stehlik 1965) comes from Tanzania (Usambara Mtns., Mombo). Only the holotype is known and it is macropterous.

Type species: *Schmitziana pilosa* Stehlik 1977
Country of origin of type species: South Africa (Transvaal)
Type depository: In the collection of J.A. Slater, Storrs, Connecticut, USA.

NEODINDYMUS Stehlik 1965

Hussey in 1929 listed 47 species in the genus *Dindymus*. Only five of these came from the Ethiopian Region, the others being either Asian or Australasian. In 1965, Stehlik re-examined the genus and decided that the African species were not congeneric with the rest, and he created the new genus *Neodindymus* Stehlik 1965 to contain them. At present the genus is considered to contain thirteen species in the Ethiopian Region, eight of which have been recorded from Eastern Africa. The NMK collection contains at least one, and probably two, species that do not correspond to published descriptions.

Type species: *Neodindymus basilewskyi* (Schouteden 1957). Designated by Stehlik 1965

Country of origin of type species: Democratic Republic of Congo

Type depository: Tervuren, Musee Royal de l'Afrique Centrale

Synonyms: *Dindymus* Stål 1861

<i>Cenaeus suspectus</i> Schout.	Stehlik 1965a: 225	

***DERMATINUS* Stål 1853**

Hussey (1929) listed ten species in the genus *Dermatinus* Stål 1853, two from India and the rest from the Ethiopian Region. However, when Stehlik (1965) re-examined specimens he came to the conclusion that many of the species were not congeneric with *Dermatinus* Stål 1853. He indicated that further revision was needed and that “with certainty” he only accepted *Dermatinus limbifer* Stål 1855 and *Dermatinus lugens* Stål 1854 as correctly placed in the genus *Dermatinus*. Since then *Dermatinus apicalis* Reuter 1881 has been transferred to *Aderrhis* by Linnauvori (1988). As matters stand at present, pending further revision, there are four species of the genus *Dermatinus* in the Ethiopian Region.

Type species: *Dermatinus lugens* (Fabricius). Quoted as a monotype by Hussey 1929, because when Stål named the genus in 1853 he did not name a type species. The type species was then named in the 1854 paper.

Country of origin of type species: South Africa.

Type depository: not known

<i>Dermatinus</i> Stål 1853	Stål 1853: 260	description

SCANTIUS Stål 1866

Hussey (1929) listed thirteen species in this genus, six from Asia, one from Madagascar, one from North Africa, and six from the Ethiopian Region. Stehlik (1965) examined many specimens from different sources and synonymised *Scantius abyssinicus* Bolivar 1879 with *Scantius forsteri* (Fabricius 1781). He also gave strong reasons for synonymising *Scantius volucris* (Gerstäcker 1873) with *Scantius forsteri* (Fabricius 1781) but it has been retained as a separate species in this paper. Here, therefore, pending further revision, five species of the genus *Scantius* are recognised in the Ethiopian Region.

The members of the genus cover almost the whole of the Ethiopian Region and *Scantius forsteri* spreads into North Africa the Middle East. There are considerable differences in morphology and color over the whole range, and this is discussed in some detail by Stehlik (1965) in respect to *Scantius forsteri*.

Type species: *Scantius forsteri* (Fabricius 1781). Quoted as a Lectotype by Hussey 1929.

Country of origin of type species: South Africa.

Type depository: not known.

Illustrations: see *Scantius caraboides* Bergroth 1920, *Scantius forsteri* (Fabricius 1781), *Scantius volucris* (Gerstäcker 1873).

Acknowledgements

I wish to express my appreciation of the help given in the preparation of this paper for publication by the late Professor R.F.Chapman of the Arizona Research Laboratories Division of Neurobiology, University of Arizona. Professor Chapman was a friend and colleague of long standing and encouraged me to finalize this catalog.

Editor's Note

Paper copies of this article will be deposited in the following libraries. Senckenberg Library, Frankfurt Germany; National Museum of Natural History, Paris, France; Field Museum of Natural History, Chicago, Illinois USA; the University of Wisconsin, Madison, USA; the University of Arizona, Tucson, Arizona USA; Smithsonian Institution Libraries, Washington D.C. U.S.A.; The Linnean Society, London, England.
