BioOne Complete (complete.bioone.org) is a full-text database of 200 subscribed and open-access titles in the biological, ecological, and environmental sciences published by nonprofit societies, associations, museums, institutions, and presses.

Your use of this PDF, the BioOne Complete website, and all posted and associated content indicates your acceptance of BioOne's Terms of Use, available at www.bioone.org/terms-of-use.

Usage of BioOne Complete content is strictly limited to personal, educational, and non - commercial use. Commercial inquiries or rights and permissions requests should be directed to the individual publisher as copyright holder.

BioOne sees sustainable scholarly publishing as an inherently collaborative enterprise connecting authors, nonprofit publishers, academic institutions, research libraries, and research funders in the common goal of maximizing access to critical research.

SUSANNE HUNGER

A survey of the genus *Pluchea* (*Compositae*, *Plucheeae*) in Australia

Abstract

Hunger, S.: A survey of the genus *Pluchea* (*Compositae*, *Plucheeae*) in Australia. – Willdenowia 27: 207–223. 1997. – ISSN 0511–9618.

The genus *Pluchea* in Australia is revised. Six endemic species, i.e., *P. baccharoides*, *P. dentex*, *P. dunlopii*, *P. ferdinandi-muelleri*, *P. rubelliflora*, *P. tetranthera* and one non-endemic species, *P. indica*, are recognized. A key to the genera of the Australian *Plucheeae* and a key to the *Pluchea* species in Australia are provided, descriptions of the species, illustrations, chromosome numbers (first records for *P. dentex* and *P. rubelliflora*: $2n = 20$) and a distribution map are presented.

Introduction

The earliest known Australian *Pluchea* collection was made by Robert Brown in 1802 during the expedition of Matthew Flinders at Broad Sound and Thirsty Sound, Queensland (specimens at BM, K). The material was later examined by Bentham (1867) for the preparation of the Flora Australiensis. He and Ferdinand Mueller validated the names of nearly all Australian *Pluchea* species.

Due to badly outlined generic delimitations and a lack of detailed investigations, taxonomic confusions surrounded the genus in Australia. One example may illustrate the problem: *Eurybia conocephala* was described by Mueller (1855), who being uncertain about the taxonomic position of this species changed its generic status several times. In 1865 he placed it in *Aster* (with the synonym *Olearia conocephala*) and finally transferred it to *Pluchea* (1887: 150) with the remark: “for including this plant in *Pluchea* it is, however, needful to extend somewhat the limits of that genus ...”. Moore (1905: 138) described a new genus, *Cratystylis*, and formed the combination *Cratystylis conocephala* (F. Muell.) S. Moore. Further studies on this genus (Anderberg & al. 1992) pointed out that it must be even removed from the vicinity of the *Inuleae* and *Plucheeae* and that its systematic position is to be found in the paraphyletic *Cichorioideae*.

There are eight genera of the *Plucheeae* in Australia; the endemic *Allopterigeron*, *Coleocoma* and *Thespidium* are monotypic, whereas *Streptoglossa* comprises eight species. The distribution of the remaining four larger genera, *Epaltes*, *Pluchea*, *Pterocaulon*, and *Sphaeranthus* is not restricted to Australia.

Following Anderberg’s cladistic analysis (1991), *Streptoglossa*, *Epaltes* and *Sphaeranthus* form together with *Pluchea* the so-called *Pluchea* clade, while *Pterocaulon*, *Coleocoma* and *Thespidium* belong to other subgroups and are rather different in habit. *Allopterigeron*, first

regarded as an uncertain member of the tribe (Anderberg 1991: 149) seems to be closely related to *Streptoglossa* (Dunlop 1981a: 168, 1981b: 186) and the herbaceous Australian representatives of *Pluchea* (Anderberg 1994: 293). Despite being one of the few *Plucheeae* taxa having marginal florets with radiate corollas, *Streptoglossa* seems to be rather close to *Pluchea* and less closely related to *Epaltes* and *Sphaeranthus*.

Today there are six endemic *Pluchea* species known from Australia. Habitually the Australian species form two distinct groups. *P. rubelliflora* and *P. dentex* are herbaceous perennials, sometimes with a woody rootstock, whereas the species of the *P. tetranthera* complex (*P. tetranthera*, *P. ferdinandi-muelleri*, *P. dunlopii*) and *P. baccharoides* are shrubs. *Pluchea rubelliflora* is the most abundant and together with *P. dentex* and *P. dunlopii* the most widespread species, while all others occur much more locally and *P. baccaroides* even appears to be rare. All endemic species possess the same number of chromosomes, i.e. $2n = 20$ (see below and Hunger 1996, there erroneously quoted as $2n = 10$). Furthermore there are two non-endemic species recorded from Australia, i.e. *Pluchea indica* and *P. dioscoridis*. Whereas *P. indica* occurs in Northern Territory and Queensland (Fig. 1), *P. dioscoridis* is recorded only from Queensland by Bailey (1900: 817) and Hnatiuk (1990: 69), but so far no specimen was seen by the author so that these records could not be confirmed yet.

Bentham (1867: 527) divided the Australian *Pluchea* species on shape of the capitula and involucre bracts in two sections, *P. sect. Pluchea* and *P. sect. Eyrea*. However, the many similarities between both groups suggest that a separation into different sections is not appropriate. Anderberg (1991: 165), on the other hand, treated the herbaceous species in his cladistic analyses as a special group, because, in his opinion, it could not be demonstrated that they belong to the same monophyletic group as the rest of *Pluchea*. Among other things he based his argument on the appressed pappus teeth of *Pluchea rubelliflora*, a feature that is, however, quite common for the genus and until now there are no reasons to exclude *P. rubelliflora* and *P. dentex* from this genus. But further studies are necessary and a comprehensive investigation of the genus and its close relatives will clarify the problems concerning the generic delimitation.

Material and methods

The present paper is part of a revision of the genus *Pluchea* in the Old World and Australia.

This study is based on field observations and collections made during an excursion in 1995 in the Pilbara Region (Western Australia), on plants cultivated from wild origin in the Botanic Garden Berlin-Dahlem, as well as on material from the herbaria A, AD, B, BM, BR, C, CANB, G, K, MEL, MO, P, PERTH, W, and WU.

Cytological preparations were made by using the standard method described by Vogt & Oberprieler (1993) with root tip tissue of plants raised in the Botanic Garden Berlin-Dahlem.

Key to the Australian genera of the *Plucheeae*

1. Capitula aggregated into dense compound secondary heads 2
 - Capitula not aggregated into dense compound secondary heads 3
2. Pappus absent, anthers tailless *Sphaeranthus*
 - Pappus present, anthers tailed *Pterocaulon*
3. Corolla of hermaphroditic florets 3-lobed, anthers 3, tailless *Allopterigeron*
 - Corolla of hermaphroditic florets 4–5-lobed, anthers 4–5, tailed 4
4. Capitula forming dense clusters along the main stem *Thespidium*
 - Capitula solitary or in terminal clusters 5
5. Pappus present 6
 - Pappus absent, or at most developed as a short rim *Epaltes*

6. Pappus of rigid scalelike bristles *Coleocoma*
 – Pappus not as above 7
 7. Achenes sericeous, capitula more than 1 cm long, marginal florets usually ligulate or corolla regularly or irregularly lobed *Streptoglossa*
 – Achenes not sericeous, capitula less than 1 cm long, marginal florets not ligulate, corolla regularly lobed *Pluchea*

Key to the Australian *Pluchea* species

1. Herbaceous growth habit 2
 – Shrubby growth habit 3
 2. Leaf bases decurrent, leaves glabrous, glandular or pilose, capitula (3.5)4.0–5.0(7.0) mm long 1. *P. rubelliflora*
 – Leaf bases not decurrent, leaves densely glandular, glands stipitate, capitula 5.0–8.0(9.0) mm long 2. *P. dentex*
 3. Plant pilose or densely tomentose 4
 – Plant not as above 6
 4. Plant densely tomentose 4. *P. ferdinandi-muelleri*
 – Plant pilose 5
 5. Leaves (0.7)1.0–2.5(3.0) cm long, obovate, obtuse or somehow truncate 5. *P. dunlopia*
 – Leaves 2.0–7.0 cm long, obovate to narrow obovate, acute 7. *P. indica*
 6. Leaves entire, linear, 0.05–0.2(0.3) cm wide 3. *P. baccharoides*
 – Leaves dentate, linear-lanceolate to obovate, (0.3)0.5–1.0(1.8) cm wide 6. *P. tetranthera*

1. *Pluchea rubelliflora* (F. Muell.) B. L. Rob. in Proc. Amer. Acad. Arts 47: 206. 1911. – Fig. 2.

≡ *Eyrea rubelliflora* F. Muell. in Linnaea 25: 403. 1853.

≡ *Pluchea eyrea* (F. Muell.) F. Muell., Rep. Babb. Exp.: 12. 1859, nom. illeg.

Type cons. prop. (Hunger 1997: 803): [Western Australia], Nickol River between Karratha and Roebourne, NW Coastal Hwy 20°48'S, 116°55'E, 19.9.1995, *Hunger & Kilian 3726* (MEL; isotypes: B, BM, CANB, K, PERTH).

Note: Caused by a misinterpretation of Mueller's original *Eyrea rubelliflora* concept, the current circumscription of *P. rubelliflora* does not include its original type material anymore. Four sheets of the original material are known to exist in Mueller's herbarium (MEL 1621087, 1621088, 1621089, 1621090) and one in W and they actually represent *P. dentex*. In order not to alter the long established nomenclature of these species, conservation of the name *Eyrea rubelliflora* with a conserved type has been proposed (Hunger 1997).

Perennial herb or subshrub up to 0.6 m high with erect branches; pilose, trichomes simple, uniseriate, multicellular; glabrous or glandular, glands sessile. Leaves 1.0–5.0(7.0) cm long, (0.1)0.3–0.7(1.5) cm wide, narrowly lanceolate to lanceolate, entire or dentate, pilose, glabrous or glandular, leaf bases decurrent, apex acute. Capitula (3.5)4.0–5.0(7.0) mm long, hemispherical, heterogamous, numerous, pedunculate, in loose terminal clusters; marginal florets female, numerous; disc florets hermaphroditic, 5–30. Peduncles (0.1)0.1–4.0(6.0) cm long, with 1–6(9) bracts reaching the capitulum. Involucral bracts in 4–5(6) rows, outer involucral bracts glabrous to sparsely glandular, 1.3–1.8(2.6) mm long, 0.4–0.7 mm wide, lanceolate, apex acute to acuminate, margin scarious; inner involucral bracts scarious, (2.8)3.0–4.2(4.5) mm long, (0.2)0.3–0.4 mm wide, linear-acute. Receptacle slightly concave, verrucose, (1.5)1.7–2.7(3.0) mm in diameter. Marginal florets 2.0–2.5(3.5) mm long, 3–4-lobed. Disc florets 2.0–3.0(4.0) mm long, 5-lobed, lobes glabrous or glandular, corolla pink; style shortly

Fig. 1. Distribution of *Pluchea dentex* [■], *P. baccharoides* [●], *P. rubelliflora* [▲], and *P. indica* [○].

divided, style branches with sweeping hairs reaching far below the bifurcation; anthers tailed, 1.4–2.0 mm long, basal appendages (0.2)0.3–0.5(0.6) mm long, apical appendages obtuse, filament collar cells swollen. Achenes sparsely hairy, terete to subangular, 0.6–0.8 mm long, 0.2–0.3 mm in diameter, with a small ring-shaped carpodium; achenes of disc florets often pale, with a broad ring-shaped carpodium. Pappus (1.6)1.8–2.5(3.0) mm long, of 6–18 free barbellate bristles in one row, caducous.

Chromosome number: $2n = 20$ (W. A., 19.9.1995, *Hunger & Kilian 3726* (B); W. A., 3.10.1995, *Hunger & Kilian 4246* (B)). The chromosome number of this species has been unknown before.

Flowering and fruiting period: (April)May to November.

Distribution and ecology

Pluchea rubelliflora is distributed in Western Australia in the Northern Province mainly in the Dampierland and the North and Central Kimberleys, in the Eremaean Province mainly in the Carnarvon and the Pilbara Region. It is scattered all over the Northern Territory, in the north of New South Wales and South Australia and in Queensland in the Dividing Ranges and at the coast near Bowen and Marlborough (Fig. 1).

Fig. 2. *Pluchea rubelliflora* – A: leaves, B: capitulum. – From Hunger & Kilian 3726 (B).

Pluchea rubelliflora is an abundant species. During a collecting trip in the Pilbara region I found this species on nearly every dry river bank and near every waterhole on sandy soil or red clayed loam. Often it grows together with *P. dentex* in the same habitat and can be mistaken for it.

Variation

Pluchea rubelliflora is a very variable species. The leaves may be strongly decurrent or only inconspicuously so. Specimens observed from the Northern Province (W. A.) have leaves which become nearly linear while many of the specimens in the Pilbara Region have very broad lanceolate lower leaves.

Occasionally plants are found with a slightly glandular indument, slightly decurrent leaves and larger capitula, and both longer and more slender involucre bracts. These plants appear to be intermediate between *P. rubelliflora* and *P. dentex*. As they have been found in mixed *P. rubelliflora* and *P. dentex* populations, they might be due to hybridization. Their achenes are normally fertile. The majority of these intermediate plants have been found in the Pilbara region (W. A.) and only a few specimens occur in the Northern Territory (for specimens, see below).

Additional specimens examined

WESTERN AUSTRALIA: Carnarvon [24°51'S, 113°45'E], *J. B. Cleland* (PERTH 532738); ca. 3.5 miles S of Yardie Creek H. S. [22°33'S, 113°51'E], 26.5.1965, *A. S. George 6619* (PERTH 532746); Lyndon R., Minilya-Learmonth rd. [c. 23°30'S, 114°00'E], 31.8.1960, *A. S. George 1450* (B, PERTH 531758); Learmonth, 22°14'S, 114°06'E, 5.9.1970, *A. S. Mueller* (MEL 1621088!); Arkaba, *F. Mueller* (MEL 1621089!); [New South Wales], Darling River, Victorian Expedition (not traced).

Note: *Pluchea squarrosa* and *P. rubelliflora* var. *major* were first listed in the synonymy of *P. dentex* by Jessop (1981).

Perennial herb or subshrub up to 1 m high, aromatic, densely glandular, seldom sparsely covered with simple uniseriate multicellular hairs; glands sessile or stipitate, 0.2–0.6(1.0) mm long. Leaves (1.0)1.5–7.0(8.5) cm long, (0.1)0.2–0.7(0.8) cm wide, linear to narrowly oblanceolate, dentate to almost pinnatifid, sessile, covered with glands, base attenuate, apex acute. Capitula 5.0–8.0(9.0) mm long, campanulate, heterogamous, pedunculate, solitary or few together in cymose clusters. Peduncles 1.0–8.0(9.0) cm long, with bracts reaching the capitulum; bracts (2.0)2.5–6.0(10.0) mm long, 0.3–0.5 mm wide, linear to narrowly lanceolate, densely glandular. Involucral bracts in 5–6 rows, loosely imbricate, outer involucral bracts 2.0–4.0(5.0) mm long, (0.3)0.5–0.7(1.0) mm wide; densely glandular, narrowly lanceolate to linear, acute, margin slightly fimbriate, inner involucral bracts (5.0)5.5–6.5(7.0) mm long, (0.2)0.3–0.5(0.6) mm wide, scarious, linear-acute, often with violet coloured tips. Receptacle slightly concave, verrucose, (2.0)2.5–2.8(3.0) mm in diameter. Marginal florets (3.0)4.0–5.0(6.0) mm long, 3–4-lobed, lobes often glandular. Disc florets 4.0–5.0(6.0) mm long, 5-lobed, lobes glandular and sometimes hairy, corolla purple; style only shortly divided, style branches with sweeping hairs reaching far below the bifurcation; anthers tailed, (0.7)2.0–2.4 mm long, basal appendages 0.3–0.4 mm long, apical appendages obtuse, filament collar cells swollen. Achenes hairy, terete, narrow at the base, (0.8)1.0–1.2(1.3) mm long, (0.2)0.3–0.35 mm in diameter; achenes of marginal florets with small ring-shaped carpopodium; achenes of disc florets pale, carpopodium broadly ring-shaped. Pappus 3.3–4.5(5.5) mm long, of 8–15(18) free barbellate bristles in one row, caducous.

Fig. 3. *Pluchea dentex* – A: leaves, B: capitulum. – From Hunger & Kilian 4036 (B).

Chromosome number: $2n = 20$ (W. A., 6.10.1995, *Hunger & Kilian 4286* (B)). The chromosome number of this species has been unknown before.

Flowering and fruiting period: May to October.

Distribution and ecology

Pluchea dentex occurs in Western Australia in the Eremaean Province mainly in the Carnarvon, the Murchison and the Pilbara Region, in the south of the Northern Territory, in South Australia in the Deering Hills, the Flinders Ranges and near Innamincka, in Queensland in the Selwyn Ranges, near Jericho and near Marlborough in the Curtis District (Fig. 1). According to Hnatiuk (1990: 69) *P. dentex* occurs also in New South Wales in the North-Western Plains. It has been found in dry creek beds, near waterholes and flood plains on red clayey loam and sandy soil.

3. *Pluchea baccharoides* (F. Muell.) F. Muell. ex Benth., *Fl. Austral.* 3: 528. 1867. – Fig. 4.

≡ *Spiropodium baccharoides* F. Muell., *Fragm.* 1: 34. 1858–59.

Syntypes: [Queensland], Belyando river, 26.[29].7.1846, *Mitchell 199* (BM 21071!, K!, MEL 1621079!); [Queensland], Suttor river, *F. Mueller* (MEL 1621080!, K!). – Lectotype (designated here): *F. Mueller* (MEL 1621080!, isolectotype: K!).

Shrub up to 1.0 m high with erect branches, older branches leafless, whole plant often vernicose, sparsely to densely glandular; glands sessile. Leaves 1.0–2.5 cm long, 0.05–0.2(0.3) cm wide, linear to lanceolate, sessile, covered with dotlike sessile glands, often vernicose, margin recurved, entire or remotely denticulate, base attenuate or prolonged into a petiole, apex acute. Capitula (5.0)5.5–6.3(6.5) mm long, obconoidal, sessile or shortly pedunculate, numerous, forming a loose to dense panicle; homo- or heterogamous; marginal florets female, 0–60; disc florets hermaphroditic, 2–30. Involucrum in 6–7(8) rows, outer and median bracts glandular, vernicose, margins scarios, fimbriate; outer bracts 1.5–1.8 mm long, 0.8–1.0 mm wide, ovate-acute; inner bracts 3.5–5.0 mm long, 0.1–0.3(0.4) mm wide, linear-acute. Receptacle slightly concave, verrucose, 0.6–0.8 mm in diameter. Marginal florets 3.0–3.8 mm long, 3–4-lobed. Disc florets 3.0–4.5 mm long, (4)5-lobed, lobes non-glandular, corolla pale purple. Anthers 1.5–2.0(2.2) mm long, basal appendages 0.2–0.4 mm long, apical appendages ± obtuse, filament collar cells indistinct. Achenes hairy, terete to subangular; achenes of marginal florets 1.2–1.6(1.8) mm long, 0.2–0.3 mm in diameter, carpodium broadly ring-shaped; achenes of disc florets pale, often vestigial. Pappus of 15–22, 2.5–4.2(4.5) mm long, free, barbellate bristles in one row; bristles of disc florets broad, 0.06–0.1 mm in diameter, with protruding and longer teeth towards the apex, apex often recurved.

Chromosome number: unknown.

Flowering and fruiting period: July–November.

Distribution and ecology

Pluchea baccharoides is endemic to Australia and occurs in New South Wales only in the north and west of Wilcannia and Wanaaring (Porteners 1992: 201), Waveley Downs and the Paroo River district (Fig. 1). According to Cunningham & al. (1981: 684) it is a rare shrub and appears to be restricted to sandy alluvial soils. In Queensland it is distributed in the area around Surbiton and Belyando River, and the Warrego River region (Hnatiuk 1990: 69). In Western Australia *P. baccharoides* has been found in the South-West Province around Esperance and the Coolgardie Goldfields.

7. *Pluchea indica* (L.) Less. in Linnaea 6: 150. 1831.

≡ *Baccharis indica* L., Sp. Pl. 2: 861. 1753.

Type: [India], Herb. Linn. 922. 8 (LINN).

Shrub up to 2 m high with erect branches; pilose, younger parts often villous, trichomes simple, uniseriate, multicellular; glandular, glands sessile. Leaves 2.0–7.0 cm long, (0.5)1.0–3.0 cm wide, obovate to narrowly obovate, entire to dentate, base attenuate, prolonged into a petiole, apex acute. Capitula (3.5)4.0–5.5 mm long, narrowly campanulate, numerous, sessile or shortly pedunculate, heterogamous, forming dense corymbose panicles, marginal florets female, disc florets hermaphroditic. Involucral bracts in 4–5 rows, outer involucral bracts pilose, sometimes glandular, (0.7)1.0–2.0(2.5) mm long, (0.5)1.0–1.5(2.0) mm wide, ovate-acute, margins fimbriate; inner involucral bracts 3.5–4.5(5.0) mm long, 0.2–0.3(0.4) mm wide, linear-acute, apex fimbriate. Marginal florets 2.5–4.0(4.5) mm long, disc florets (2.5)3.0–4.5(5.0) mm long, 4–5-lobed; style branches with sweeping hairs reaching far below the bifurcation; corolla pale purple; anthers tailed. Achenes glabrous to sparsely hairy, slightly heteromorphic; achenes of marginal florets 0.7–1.0 mm long, 0.2–0.3 mm in diameter; achenes of disc florets either 0.6–1.0 mm long, 0.2–0.4 mm in diameter, pale, or often vestigial. Pappus of 18–20(25) free, barbellate bristles in one row.

Variation and chromosome numbers

Pluchea indica is a very variable species with a tendency to hybridize (Cooperride & Galang 1965) which could probably explain that there are different chromosome numbers published, i. e. $n = 15$ [India: West Bengal *Howrah* (CBL H 14050)] (Sarkar & al. 1982), $n = 30$ [Pakistan:

Makran, *T. Ali* 892; Karachi University, Campus, *Jahan* 7,8] (Razaq & al. 1994) and n = 10 [Pacific islands, *Cooperrider* 9255 (KE)] (Cooperrider & Galang 1965).

Flowering and fruiting period: (March) April to November.

Distribution and ecology

Pluchea indica is an Australasian species, distributed from India and S China throughout Indochina, the Philippines to Australia and the Pacific islands. In Australia it is known from the Northern Territory and Queensland (Fig. 1), near riversides, amongst mangrove vegetation, on saline clay pans and on the edge of tidal creeks.
