BioOne Complete (complete.BioOne.org) is a full-text database of 200 subscribed and open-access titles in the biological, ecological, and environmental sciences published by nonprofit societies, associations, museums, institutions, and presses.

Your use of this PDF, the BioOne Complete website, and all posted and associated content indicates your acceptance of BioOne's Terms of Use, available at www.bioone.org/terms-of-use.

Usage of BioOne Complete content is strictly limited to personal, educational, and non - commercial use. Commercial inquiries or rights and permissions requests should be directed to the individual publisher as copyright holder.

BioOne sees sustainable scholarly publishing as an inherently collaborative enterprise connecting authors, nonprofit publishers, academic institutions, research libraries, and research funders in the common goal of maximizing access to critical research.

Gastrointestinal Helminths of Fish-Eating Birds from Chiloe Island, Chile

Patricio Torres, Eileen Ruíz, Walter Gesche, and Aldo Montefusco, Institute of Parasitology, Universidad Austral de Chile. Valdivia. Chile

ABSTRACT: Of four species of fish-eating birds from Chiloé Island (Chile), three were infected with eight species of helminths. Tetrabothrius sp. was found in Larus scoresbii. Tetrabothrius cylindraceus, Profilicollis antarcticus, Anomotaenia dominicanus, Stephanoprora denticulata, Capillaria sp. and P. antarcticus were found in Larus dominicanus. Contracaecum rudolphii and Corynosoma sp. infected Phalacrocorax olivaceus. With the exception of S. denticulata, C. rudolphii and Capillaria sp., the above helminths are reported for the first time from Chile.

Key words: Helminth parasites, piscivorous birds, Larus spp., Phalacrocorax olivaceus.

Helminthological data on fish-eating birds of Chile are scarce (Torres et al., 1982, 1983a). Thus, in April 1989, 10 fish-eating birds were examined for gastrointestinal helminths as part of a research project in southern Chile at Lake Huillinco, Lake Natri, and the coastal zone of Yaldad, all on Chiloé Island (Table 1; between 42°30′ and 43°15′S).

The birds were killed by shotgun; the gastrointestinal tract was removed, kept at 4 C, and then within 4 hr examined for helminths (Torres et al., 1974). Helminths were preserved following techniques in Pritchard and Kruze (1982); cestodes and trematodes were dyed with Semichon's Acetic Carmin and Malzacher's stain.

With the exception of Stephanoprora denticulata, Contracaecum rudolphii and Capillaria sp., these helminths are reported for the first time in Chile (Table 1). In addition, Profilicollis antarcticus is recorded for the first time in Larus dominicanus; this acanthocephalan was described from Chionis alba (Gmelin) of the Shetland Islands (Antarctic) (Zdzitowiecki, 1985). Chionis alba lives in the Magallanes Strait and coasts of Tierra del Fuego up to Antarctica and migrates occasionally to Chiloé (Araya and Millie, 1986).

Anomotaenia dominicanus and Tetrabothrius cylindraceus have been recorded in *L. dominicanus* on the Falkland Islands (Odening, 1982) and in the Antarctic (Zdzitowiecki and Szelenbaum-Cielecka, 1984).

Contracaecum rudolphii was earlier reported in South America and Argentina (Szidat and Nani, 1951) and in Chile (Torres et al., 1982, 1983a) in Phalacrocorax olivaceus and Larus spp. The wide geographic distribution of C. rudolphii (Barus et al., 1978) and S. denticulata (Torres et al., 1983b) is related to the migration of some of their numerous definitive hosts; as in the case of C. rudolphii wide distribution may be attributed to the wide range of fishes that act as intermediate hosts.

Larvae of Contracaecum multipapillatun Von Drasche, 1882 have been reported in fish (Mugil cephalus) in the north of Chile (Fernández, 1987), but the definitive host has not been determined in this area.

In different fresh-water ecosystems of the south of Chile the infection by larvae of Contracaecum sp. in introduced (Torres and Cubillos, 1987) and autochthonous fishes (Torres et al., 1988) has been established. The predation, consumption of viscera, or spread of these fish by the fishermen is possibly contributing to the infection of the fish-eating birds which act as definitive hosts.

Stephanoprora denticulata was reported previously in *Podiceps major* and *Pelecanus thagus* in the Valdivia River estuary (Torres et al., 1982).

The material collected was deposited in the collection of the Institute of Parasitology, Universidad Austral de Chile, Valdivia, Chile (IPUAT N° 0038-0048).

This study was supported by Grant N° 0069/1989 (FONDECYT) and Project N° S-89-17, Dirección de Investigación, Universidad Austral de Chile. We thank R. Schlatter (Institute of Zoology, Universidad Austral de Chile) for his help in the identification of birds, and the Centro de
