The BioOne Digital Library (<https://bioone.org/>) provides worldwide distribution for more than 580 journals and eBooks from BioOne's community of over 150 nonprofit societies, research institutions, and university presses in the biological, ecological, and environmental sciences. The BioOne Digital Library encompasses the flagship aggregation BioOne Complete (<https://bioone.org/subscribe>), the BioOne Complete Archive (<https://bioone.org/archive>), and the BioOne eBooks program offerings ESA eBook Collection (<https://bioone.org/esa-ebooks>) and CSIRO Publishing BioSelect Collection (<https://bioone.org/csiro-ebooks>).

Your use of this PDF, the BioOne Digital Library, and all posted and associated content indicates your acceptance of BioOne's Terms of Use, available at www.bioone.org/terms-of-use.

Usage of BioOne Digital Library content is strictly limited to personal, educational, and non-commercial use. Commercial inquiries or rights and permissions requests should be directed to the individual publisher as copyright holder.

BioOne is an innovative nonprofit that sees sustainable scholarly publishing as an inherently collaborative enterprise connecting authors, nonprofit publishers, academic institutions, research libraries, and research funders in the common goal of maximizing access to critical research.

Syndactylism and Brachygnathia in a White-tailed Deer

Edward A. Rollor, III, Southeastern Cooperative Wildlife Disease Study, College of Veterinary Medicine, The University of Georgia, Athens, Georgia 30602, USA

ABSTRACT: A white-tailed deer (*Odocoileus virginianus*) fawn was presented to the Southeastern Cooperative Wildlife Disease Study for examination of brachygnathia and syndactylous front feet. The hoof keratin of digits 3 and 4 was completely fused and typical sole integument covered the palmar surface between the primary digits. Based on a radiographic examination, there was fusion of the epiphyses of the first phalanges of digits 3 and 4 in both feet. In

the right foot the proximal metaphyses of the first phalanges of digits 3 and 4 were fused.

Key words: *Odocoileus virginianus*, white-tailed deer, brachygnathia, syndactylism.

On 6 June 1979 a 12-day-old (Haugen and Speake, 1958), female, white-tailed deer (*Odocoileus virginianus*) with syndactylous front feet and brachygnathia was

submitted to the Southeastern Cooperative Wildlife Disease Study, Athens, Georgia (USA), for examination. The fawn was found in Wayne County, Georgia (31°40'N, 81°50'W). The deer was in good condition and did not exhibit difficulties in walking or eating. The incisors of the lower jaw met the upper jaw approximately 1 cm behind the normal point of contact. The hoof keratin of both front feet was completely fused at the interdigital clefts of the primary digits (digits 3 and 4). The palmar surface of the fused primary digits was covered with typical sole integument (Fig. 1A). Based on a radiographic examination of the right front foot, there was a fusion of the epiphyses and the proximal metaphyses of the first phalanges of digits 3 and 4 (Fig. 1B). The left front foot did not have a fusion of the metaphyses of the first phalanges, but did have a fusion of the epiphyses of the first phalanges (Fig. 1C).

Three cases of syndactylous feet in roe deer (*Capreolus capreolus*) (Szabo, 1965, as cited by Saperstein et al., 1978) and one case in a South American deer (*Odocoileus virginianus peruvianus*) (Lonnberg, 1930, as cited by Harris, 1975) have been reported. Syndactylism has not been reported previously in North American cervids.

Brachygnathism has been reported in mule deer (*O. hemionus*) (Robinette and Aldous, 1955; Short, 1964) and white-tailed deer (Johnson, 1935; Ryel, 1963; Scanlon, 1973; Wobeser and Runge, 1973; Barrett and Chalmers, 1975; Smits and Bubenik, 1990). Reports of limb deformities other than syndactylism accompanied by brachygnathia have been arthrogryposis (Barrett and Chalmers, 1975), limb rotation (Scanlon, 1973; Wobeser and Runge, 1973), and osteopetrosis (Smits and Bubenik, 1990). Smits and Bubenik (1990) suggested that inferior brachygnathia may be a phenotypic marker for the lesions of osteopetrosis and should be considered in populations where inbreeding occurs.

This study was supported by an appro-

priation from the Congress of the United States to the Southeastern Cooperative Wildlife Disease Study, College of Veterinary Medicine, The University of Georgia, Athens, Georgia. Funds were administered and research coordinated under the Federal Aid to Wildlife Restoration Act (50 Stat. 917) through Contract Number 14-16-0004-99-916, Fish and Wildlife Service, U.S. Department of the Interior. The author is grateful to Dr. Royce E. Roberts, Dr. Lynn E. Hayes, and Dr. Gail L. Mahnke for their interpretations of the radiographs.
